LETTERS TO THE EDITOR

The football club doctor system

EDITOR,—I read with interest the paper by Waddington et al. highlighting the inadequacies of the football club doctor system in Britain. This paper confirms the situation that many people already knew to exist. Advertisements for club doctors are rarely published in medical journals, doctors normally being appointed on a “who you know” basis. It is also particularly disappointing that, at a time when any speciality of sport and exercise medicine is being established in this country, the majority of doctors working with professional footballers have no qualifications or little experience in the specialty. However, it is not confined to football clubs and probably also applies to rugby clubs and many other sporting associations.

One aspect not mentioned in the paper is medical litigation. It is to be hoped that doctors involved with football clubs have arranged medical defence cover, because, if a situation arises in which a player’s sporting career is threatened by medical mismanagement and the doctor involved has no professionally recognised sports medicine qualification, he or she could be found guilty of medical negligence. With the amount of money involved in professional football, this could have dire consequences for the medical career of the practitioner involved.

From a report commissioned by the Football League on the Hillsborough tragedy, the concept of the “crowd doctor” was introduced, meaning that any doctor involved in the medical care of the crowd at a football stadium would be required to possess at least the Diploma in Immediate Medical Care. Before that, the situation was similar to that of the present club doctor system, and few doctors held any recognisable qualifications or training in medical emergencies and resuscitation.

A similar recommendation by sports medicine authorities is required to enhance the quality of service provided to football clubs and increase the stature of the specialty. However, it is not a one-sided situation. Football clubs must realise that the importance of a medical team in looking after their prime assets, the players. Advertising of jobs in medical journals, insisting on experience and qualifications, adequate remuneration, and the provision of job descriptions and contracts should all be implemented. By working together to improve the current situation, a service can be provided in which both professional football players and the medical profession can have confidence.

S BOYCE

Authors’ reply

We welcome Dr Boyce’s letter as a useful contribution to the debate generated by our article. Dr Boyce is quite correct to raise the issue of medical litigation. As the American College of Sports Medicine pointed out as long ago as 1991, what it called “the litigation epidemic” had at that time already “begun to engulf sports medicine” in the areas of negligence and malpractice, informed consent, counseling, re-entry to play decisions, and other matters. It is probable that we shall in future increasingly see such cases in the United Kingdom, and the club doctor without an appropriate specialist qualification may be held to be more at risk in such cases.

Dr Boyce is also correct to draw attention to the fact that, for the past 10 years, the “crowd doctor” at professional football matches has been required to hold a recognised specialist qualification in Immediate Medical Care. The fact that club doctors are not required to hold a comparable and appropriate specialist qualification is an anomaly that needs to be addressed as a matter of urgency by sports medicine authorities, by clubs, and by the Football Association. It goes without saying that he is also correct to point to the need for football clubs to adopt more realistic policies regarding the provision of doctors, namely the health—and therefore also the playing ability—of their players.

Finally, we fully accept that, as Dr Boyce suggests, the situation that we documented in our article is an anomaly that needs to be addressed as a matter of urgency by sports medicine authorities, because, if a situation arises in which a player’s sporting career is threatened by medical mismanagement and the doctor involved has no professionally recognised sports medicine qualification, he or she could be found guilty of medical negligence. With the amount of money involved in professional football, this could have dire consequences for the medical career of the practitioner involved.

Sports medicine clinics on the NHS: a patient survey

EDITOR,—Following the recent success of the British team at the Sydney Olympics, media and medical attention appears to be preoccupied with the health and welfare of the “elite athlete”. However, the overwhelming majority of people who participate in sport in this country are not at an elite level. In fact, the term “athlete” may not even be correct. Many people who participate in sport for the physical benefits of exercise and the personal enjoyment that it brings.

When people are acutely injured, their first port of call is their GP or local A&E department. If physiotherapy is required, there is often a lengthy waiting period. For chronic or overuse injuries, the GP may not have the time, inclination, or qualifications to deal competently with their management. The opinion of an orthopaedic consultant is desired, six months or more may elapse before an appointment. Further time will be lost in waiting for investigations and/or surgery. For the “ordinary” sportsperson, over a year may pass before they can return to their sport for an injury that may be resolved in one to two months for an “elite athlete”. Of course, if a local privately run sports medicine clinic exists, specialist input and quicker treatment can be offered, bypassing the NHS waiting lists. But this costs money and not everyone can afford to pay for healthcare.

We randomly selected 40 people who attended the A&E department with a sports injury and were discharged to the care of their GP for follow up. A questionnaire was sent to each patient asking them “if a specialist sports medicine clinic was present at the hospital would you have preferred your injury to have received further treatment at this clinic rather than your local GP practice?”. A response rate of 47.5% was obtained, 99% would have preferred their injury to be reviewed at a sports medicine clinic. Various reasons were given for this preference, with many feeling that their GP was not interested or knowledgeable enough to deal with their problem correctly. Most also felt that at a sports medicine clinic they would be treated by specialists in their field similar to that of any other hospital specialty outpatient clinic.

Although this survey targeted a possibly biased group, these are the majority of people with sporting injuries that we should be aiming to treat. The introduction of NHS based sports medicine clinics may be a few years away but the training of doctors to a specialist standard through regulated training schemes must start now.

New Zealand Olympic experience—Sydney 2000

EDITOR,—New Zealand’s Olympic medical team of four doctors, seven physiotherapists, one chiropractor, one massage therapist, and a sports psychologist provided medical care for a team of 150 athletes and 76 officials at the Sydney Olympic Games. During the month in Sydney, we provided consultations and 1403 physiotherapy and chiropractic treatments, plus numerous massages.

All but one athlete was able to compete in their chosen event. For the athletes who required laboratory investigations or imaging, a comprehensive service was provided at the polyclinic within the Olympic Village. Special mention should be made of the superb organ imaging service organised by Dr Jock Anderson. Readers of this Journal may be interested to know of the rapid response to CT guided nerve root sleeve injections of corticosteroid. Three of our athletes with lumbar nerve root signs had these injections, and all were able to compete some 48 hours after injection. This epitomises the high standard of diagnostic and therapeutic intervention that was possible, and the impressive clinical results that could be achieved.

In summary, the Olympics represent the pinnacle of sporting excellence and I am pleased to report that the medical facilities available to athletes in Sydney were of the same high standard as the achievements of the competitors.

Reassessing the need for sport diving medicals

EDITOR,—Dr Stephen Glen and his coauthors conclude from an analysis of medical records held by the Scottish Sub-Aqua Club (SSAC) that routine medical examinations of sport divers can safely be replaced by a system of self-declaration, with a questionnaire designed to indicate whether referral to a doctor with experience of diving medicine is necessary. The conclusion should be regarded as preliminary, however, because the data were not disaggregated sufficiently to reveal the additional screening value of a routine medical examination beyond that of an initial questionnaire. In addition, there are inherent statistical biases in the SSAC data that have not been addressed.

The risks associated with discontinuing routine examinations could have been investigated by quantifying the number of cases in which disqualifying conditions were found in medical examination but not declared in the prior questionnaire. However, the authors’ listing of abnormalities recorded at examination appears to include those due to conditions declared in the questionnaire. Similarly, the listing of formal referrals to approved medical referees does not indicate how many were initiated by a questionnaire response and how many as a result of an examination ending only. Crucially, the cases that were ultimately failed were not classified by type of disqualifying condition or by stage at which the condition was first detected. The prevalence of disqualifying conditions that subjects were unaware of, or otherwise did not declare, before the examination is therefore obscured.

Under the SSAC system during the study period, general practitioners could certify candidates with certain conditions as “ unfit to dive”, without referring them to a medical referee. As a certificate of fitness to dive was a prerequisite of membership of the SSAC, these subjects would not join the organisation and details of their medical examination would be unlikely to enter the medical database. The discriminatory value of medical examinations may therefore have been underestimated if it may have been reported that subjects were failed outright without a medical referee being consulted (when their details would be more likely to enter the database), but that eventuality should be considered and probably quantified.

The data set is also biased by the inclusion of “repeat” medicals (routine periodic re-examination of divers), which comprised nearly 30% of the records analysed. This probably involved some degree of pseudo-replication, but even if there was only one record for each individual, one may expect a lower prevalence of disqualifying conditions among a group who had previously been certified “fit” than among first-time applicants. The prevalence of disqualifying conditions among new applicants therefore needs to be estimated separately.

The authors may be correct that routine medical examinations for sport divers are unnecessary, but if policy on such an important safety issue is to be changed, the justification for doing so should be clearly demonstrated and qualified according to the limitations of the available data.

Authors’ reply

The main conclusions of our paper were that no significant improvements were found on clinical examination of divers in the Scottish Sub-Aqua Club, and that the questionnaire was the important part of the screening assessment of divers. This remains the case regardless of how the information is analysed.

In response to the questions raised by Philip Smith, only 391 divers responded “No” to all questions, and none had abnormalities on clinical examination. All of the referrals to medical referees were prompted by positive questionnaire responses, and the divers were assessed by doctors with diving medicine experience. The interim step of clinical examination by a doctor without such experience did not affect the final outcome.

Divers start training with the SSAC by undergoing basic snorkel and rescue training (as with most diving organisations) and may progress to scuba training after a medical examination. They entered the SSAC system during the snorkel training, however, and in our experience GPs did not fail divers outright before contacting SSAC headquarters or a medical referee. It is not possible to confirm that all divers were referred in this way, but it is reassuring that an analysis of the medical forms after the introduction of a self-certifying system has confirmed an increase in the number of divers failing on the basis of questionnaire responses alone.

It was necessary to include the repeat medicals in the analysis because the introduction of a new system must be as effective in the existing divers as it is in the new entrants. New medical conditions may develop in the period between medicals, which can be up to five years. Removing the repeat medicals from the analysis does not affect the final conclusion, which confirms that the questionnaire is the most important part of the screening process.

A new questionnaire system was introduced in March 2000 and analysis of the short term data has shown a slight increase in the number of divers failing their medical assessment. A complete report will be submitted for publication shortly. In addition, all forms submitted by divers are now reviewed by diving doctors, and assessment is only performed by doctors with diving medicine experience. This helps to ensure a consistent application of the medical standards recommended by the UK Sport Diving Medical Committee. There has been no change in the incident pattern although it is too early to expect major differences to become apparent.

It is worth noting that the role of routine medical examinations has been questioned elsewhere, and that the number of diving accidents related to medical conditions did not significantly change when compulsory medicals were introduced in Australia and New Zealand.1 The only problem in assessing fitness to dive has been the fact that divers have been assessed by doctors without diving medicine experience, and the introduction of the new system has allowed this to be rectified. Divers should not be falsely rectified by the value of a screening medical examination performed by a doctor without diving medicine experience.

Management of diabetes at high altitude

EDITOR,—In response to the leader of Moore et al., we would like to report the results obtained in eight type 1 diabetic mountainers who ascended the Aconcagua (6950 m)1 without any significant medical problems. The only climber unable to make the summit, because of a problem not related to diabetes, reached 6700 m.

None of the climbers took any drugs to prevent acute mountain sickness (AMS) because of the possible risks. Instead, they acclimatized gradually. Above 5000 m some of the diabetic climbers experienced hypoglycaemia after dinner with nocturnal hyperglycaemia probably because of delayed absorption of the Insulin Lispro. The climbers ascended to altitude and rapid absorption of the Lispro Insulin used by most of the group. We recommended delaying the administration of insulin until the end of dinner.

There were no problems with glucometers. The devices were protected with home made bags and carried next to the skin.

As expected, all members of the team suffered bouts of hypoglycaemia and hyperglycaemia but were managed successfully. Glycaemia was monitored on average seven times a day. The expedition doctor had to intervene in only one case of medium postprandial hyperglycaemia at 5000 m.

In a previous investigation of type 1 diabetic climbers, 15 out of 24 of the climbers reached altitudes above 5000 m (three above 7000 m). None reported major complications at altitude nor taking any drugs to prevent AMS. In climbs under 3000 m, hyperglycaemia caused by dehydration (two cases) or extensive sunburn (one case) were reported; all were self managed and resolved before the climbers reached hospital. One climber had previously measured his glycaemia at a height of 8200 m on Mount Everest. He tested the glucometer in the hypobaric chamber at 5000 m without any significant differences from sea level.

Optimal management of the diabetes, together with progressive acclimatisation, was the key to success. All the team were good at self monitoring under any conditions and had the skill to calculate insulin and carbohydrates and the ability to handle early hyperglycaemia and hypoglycaemia.

Climbing mountains at high altitude is a risky sport. Diabetic climbers should not be deterred from going to altitude provided that they are aware of the increased risks and the importance of frequent self monitoring and gradual acclimatisation to avoid AMS.

The future for the field of sports medicine

EDITOR,—Can I begin by expressing my appreciation for the introductory free access to the journal since its launch on the web earlier this year. This year I have undertaken an intercalated degree in clinical medicine which has been offered by the Department of Medicine and Therapeutics at Glasgow University for the past four years. Over 60 of my fellow students opted to do the same. We each, however, opted to do a specialist module in addition to a common core course. The options include cardiovascular studies, clinical neuroscience, and cancer studies. I chose to do sports medicine, largely because of my own interest and participation in sport. Indeed participation in sport was a common factor among the 10 students opting for this module. Admittedly many of us felt that this, compared with some of the other modules, would not be a particularly taxing option. Our reputation as “slackers” among the rest of the year group was evident. As far as they were concerned we were always assured in fun things while they grappled with the serious issues at the cutting edge of medical research! However, although I have thoroughly enjoyed the lectures, this was by no means the easy option, and I agree wholeheartedly with Paul McCrory that it is about time attitudes changed.

Who says there are no serious issues in this field? Consider the dilemma of the physician who has been pleaded with to give a pain killing injection to a young player, with the risk of more serious damage, because an international scout will be at this match and this may be his only chance to make an impression. Consider also the responsibility, swift judgment, and strength of character impressed. Who says there are no serious issues in this field? Consider also the responsibility, swift judgment, and strength of character impressed. Who says there are no serious issues in this field?

The elite athlete has emerged as someone with specialist medical needs, and we need specialist sports medicine physicians to respond. But the field of sports medicine goes far beyond these more traditional roles into a wide range of other specialties: cardiology, respiratory medicine, gynaecology, rheumatology, neurology, to name but a few of the areas our lecturers have explored. We need specialists who can advise in each of these areas but to enable them to do so we need to provide them with the necessary evidence base.

What has been most evident throughout is the requirement for more well conducted research and clinical guidelines based in this field. We are a generation of medical students who have been pleased to give a pain killing injection to a young player, with the risk of more serious damage, because an international scout will be at this match and this may be his only chance to make an impression. Consider also the responsibility, swift judgment, and strength of character impressed.

BOOK REVIEW

This clinical companion is a reference text for physiotherapists, which attempts to cover all aspects of clinical care as encountered by this clinical group. It has a strong American bias and aims, using a broad based clinical approach, to provide physiotherapists with relevant information so that they have a thorough understanding of patients’ conditions.

My first impression of this book is that it is compact and well structured with an interesting and diverse contents list. Information is easily accessed from its 15 chapters, which focus mainly on assessment, measurement, and rehabilitation, with a clear description of the contents of each section.

The format is logical and easy to read with an abundance of diagrams and illustrations. However, at some points in the book, the charts appear infinite and interrupt the text for longer than my concentration would allow. The book stimulates the reader to browse through the pages for light reading, but, although the extensive topic content is impressive, the detail is disappointing.

My interest in the book was in the musculoskeletal content which proved lacking. Common disorders encountered in an outpatient setting accounted for one third of one chapter, and the treatment it recommends for low back pain and manual handling manoeuvres would not be keeping with current clinical effectiveness guidelines in the United Kingdom.

Other areas covering diagnostic tests, signs and symptoms, and outcome measures are covered succintly for physiotherapists.

Letters, Book reviews, Calendar, Notes

3 Pugh KT. How high is Kilimanjaro? Tanganjina Notes and Records (Journal of the Tanganyika Society) 1965;No 64:144-6.
The text fulfils its role as a quick reference guide for junior staff or students; however, it is a little overambitious in its diversity and is non-specific in relation to relevant physiotherapy practice.

**NOTES AND NEWS**

**Online advice for sportswomen**

Sports Medicine Australia’s fact sheets containing health information for sportswomen can now be accessed online. Covering topics such as premenstrual syndrome, exercise and pregnancy, and osteoporosis, the fact sheets can be downloaded free of charge from http://www.sma.org.au/sma/women.html

**Australia recognises sports physicians**

The Australian government’s Health Insurance Commission (HIC) has granted sports physicians with a Fellowship of the Australian College of Sports Physicians access to their own Medicare item numbers. This recognises sports physicians as a separate entity from general practitioners and restores their rebate to the equivalent of a vocationally trained GP. This is the first time the HIC has recognised a “special group” and is a significant step forward in the quest for full specialist recognition. This process is about to resume now that the Australian Medical Council has established a new process for recognition of new specialties.
