Two recent reviews have concluded that little is known of the psychological effects (advantageous or otherwise) of wearing protective equipment in rugby. The most common reasons for wearing protective equipment given by participants in a New Zealand study were: to prevent injury (57%), because of previous injury (53%), and because of medical advice (21%). Australian schoolboy rugby players also cited safety as the primary reason for using headgear and reported that they played more confidently when wearing headgear.

On the basis of their conclusions regarding the impact of padded equipment on the incidence of injury, Garraway et al recommend that the International Rugby Board “place a moratorium on the further development of protective equipment until it has been established that it is not contributing to the substantial increase in player morbidity associated with the introduction of professional rugby union.” In their abstract, they go further by recommending that the moratorium should be placed on the “use of protective equipment in competitive matches”.

There is present little evidence to suggest that padded equipment modifies the risk of injury in rugby. We have no argument with the need to find explanations for the disturbing increase in injury reported by Garraway et al. What concerns us is that their recommendations have been made in the absence of supporting evidence, and that in making such recommendations attention is diverted from other explanations for the observed increase in injuries, such as law changes that affect the way in which rugby is played. Investigation of the effects of padded equipment on injury risk, through well designed research, is required before recommendations about its use can be made. Placing a moratorium on the use of protective equipment may make it difficult to undertake such research.

Authors’ reply

Thanks to David Humphries for his comments on our paper. We agree that our respondents may have overestimated the time they spent leading and bouldering in comparison with top roping, although, if this is the case, we should ask why. Bravado, perhaps wishing to appear bolder than they actually are, or memory error, seem the most likely explanations. Memory error, resulting in this case in misclassification bias, is a potent source of error in epidemiological studies, a bias to which our study is no less susceptible than others reliant on memory-based replies.

If the misclassification is all in one direction—that is, some people stated that their most common activity was leading and bouldering when it was in fact top roping, and no one made the opposite error—the true odds ratio for leading and bouldering in comparison with top roping would be lower than that which we found. We have not performed a sensitivity analysis to estimate the degree of misclassification time spent on these activities that would reduce the coefficient of this variable to non-significance.

We have one further comment to make in relation to Humphries’ remarks about “committed” climbers. We have already pointed out that we cannot regard our sample as a true cross sectional representation of the indoor climbing population. In particular, it seems unlikely that “team building” clients in an expanding market. In this sense, we suspect that almost all our respondents would be “committed” climbers, but the word has a different sense here from the way Humphries has used it.

Sports doctors’ resuscitation skills

EDITOR—I cannot resist the temptation to join the debate on sports doctors’ resuscitation skills.1 The study by Thompson et al2 suggested that there is a perceived need among sports specialists for first aid skills. However, I received no response to my letter concerning this which indirectly posed the question, “should doctors who attend aquatic sports be able to deal with a suspected cervical spine fracture and recover the casualty?”

Obviously, that is the task of a lifeguard in the same way that first aid at non-aquatic events is the task for a first aider, but perhaps doctors should be competent first aiders and/or lifeguards. This was never in the medical school curriculum and perhaps that should change. At least, first aid training is part of sports medicine courses, but I would like to suggest that lifeguarding should also be included. I would also suggest that all doctors at aquatic events should hold the NLPLQ, NBLQ, or at least bronze medallion and bronze cross of the RLSS or overseas equivalent.

Should the organisers of any sports medicine course want advice on this, they should contact the RLSS at River House, High St, Broom, Akester, Warwickshire B50 4HN, UK. I would be happy to help out but would make two stipulations: everyone on the course should have a proper first aid qualification and they should sponsor me for my next fund raising event for the RNLI.

BOOK REVIEWS

This is the best book on the marathon that I have ever read. It is composed of a series of chapters based on lectures delivered at a British Heart Foundation symposium on marathon medicine held in London in 2000. The content includes a wide range of disciplines: history, sociology, psychology, medicine, physiology, and more.

It is noted in the introduction that the reader will be treated to the views of a veritable galaxy of experts. This is no false claim.

What a pleasure it was to read this book—comprehensive, direct, accessible, and practical—are only a few relevant adjectives applicable to this text. It even kept me awake on a Sydney to London flight! Beautifully presented with clear figures, singular in its lack of waffle, and very well referenced, this is the ultimate guide to so many aspects of what many consider to be the greatest race. In addition to the wealth of information contained in the chapters proper, I quite appreciated the inclusion of short sections of discussion between conference attendees and the experts which were included at the conclusion of some chapters.

Having personally struggled through a number of these events, I especially looked for practical information. Will it kill me? Probably not. Will I live forever if I complete one? No. What should I drink and eat? What about altitude training? Why do I fatigue? The answers, or our best current knowledge, are all there.

This is an excellent book. I am half way through it on the second reading. I would buy it myself and recommend it to all of those who care for participants in, or who are interested in, endurance sport. It is suitable for sophisticated athletes and both students and practitioners of sports science and sports medicine.

“We have tried to strike a balance between being too academic on the one hand and competing with the pocket guides on high altitude emergencies on the other” proclaim Michael Ward, James Miledge, and John West, three internationally respected authors on the subject of high altitude medicine. Their third edition is an attractively covered book, its surrising weight giving suitable notice of the serious reading within.

Each chapter starts sensibly with a list of contents followed by a carefully worded summary. I found this increasingly useful as the majority of text favours the clinical specialist and high altitude physiologist. By chapter six I was struggling with M = (P – Pₐ) Q(1 – e⁻Φ) o. Those of you who recognize this as relating to the total transfer of a gas will be at one with this book. I suspect the majority of readers will silently thank the authors for providing those chapter summaries.

In the midst of this text I could sense John West’s influence predominate, with the profusion of scientific tables and graphs sprinkled with references to the pioneers of high altitude physiology, and it was in these scientific chapters that the authors seemed most at ease. As a GP with an interest in mountain rescue, I found the latter third of the book much more relevant. The conditions of high altitude pulmonary oedema and cerebral oedema (HAPE and HACE), hypothermia, exhaustion, and fatigue are covered in workable detail, and there is useful information on how clinical conditions such as diabetes, COPD, and IHD are affected by high altitude.

So have the authors succeeded in their aim? On balance this is more of interest to the research scientist or high altitude specialist rather than readers like myself. There are cheaper (much) books that cover the clinical aspects at least as well, but none so logically laid out, beautifully presented, or as thoroughly researched (I counted 1557 references!). One for the serious high altitude buff who won’t even see the price tag.

I was excited when I saw this book as the five authors are all well known to me as prominent in their respective fields. Nicola Maffulli of Stoke on Trent via Aberdeen and Hong Kong is an orthopaedic surgeon with a special interest in children’s injuries, Kai Ming Chan from Hong Kong is a widely published orthopaedic surgeon, Rose Mc-Donald has been prominent in sports physiotherapy in the United Kingdom for many years, Bob Malina from Michigan State University is one of the foremost experts in children’s growth, and Tony Parker has been a leading FIMS official for many years.

Their stated aim is “to address in one volume the specific problems of different categories of individuals in sport”. The four groups considered were the young, the old, the female athlete, and the disabled athlete—all important subgroups with specific problems of their own. These four groups usually get a chapter each in general sports medicine books, so one would hope that these areas would be considered in significantly more detail in this publication.

The children’s section covers all the important issues such as growth and matura-
tion, strength and endurance training, nutri-
tion, and competitive stress. The sections on injuries have some inaccuracies—for example, in the section on navicular stress fractures describing the pain as “well localised to the apex of the foot” and prescribing rest only in the treatment, and the use of a rigid Boston brace in all cases of spondylolysis—but they are generally well covered.

The female section also covers all the major issues but is quite repetitive, with three different chapters all covering menstrual irregularities. The section on ageing and mas-
ter athletes (surely that should be masters

Clinical risk management is a strange subject, and I would recommend that clinicians read the specific chapter. In future editions, this area of the book I am sure is destined for bed time reading, it is a book that every clinical risk manager should have access to, and I would recommend that clinicians read their specific chapter.

In all, this book covers important areas but suffers from too much repetition and poor editing. I am not sure that it covers the topics much better than some of the good sports medicine texts.

NOTES AND NEWS

www.basem.co.uk
The British Association of Sport and Exercise Medicine has launched its new website—www.basem.co.uk. The site provides information on the educational opportunities in sport and exercise medicine, and advice to those wishing to be involved in this area. BASEM members can also access the latest information of BASEM events.

www.UKSI.net
The UK Sports Institute (UKSI) is currently developing a password restricted website—www.UKSI.net—for the elite professional sporting community including athletes, coaches, and those in sport science and medicine. The site will be commissioning experts to write articles on a variety of topics. Each article will be aimed at the entire audience, promoting the integrated philosophy of the UKSI.

Bayesian statistics and evidence based medicine
Evidence based medicine is the buzzword of the day. But in fact, the standard statistics that are used in almost all studies do not answer the questions that are of interest to the clinician, even though they are misinterpreted as if they do. A new website www.physio.mcgill.ca/smcourse/bayesian is now available that compares the inferences that can be drawn from standard statistics with those that can be drawn from the Bayesian statistical approach. The authors welcome all questions and comments. This site is designed for both clinicians and epidemiologists.
