A strategy to reduce illicit drug use is effective in elite Australian football

Peter R Harcourt,1 Harry Unglik,2 Jill L Cook3

ABSTRACT
Background The World Anti-Doping Agency (WADA) prescribes that drug testing is conducted in sports competitions to detect drug use in athletes. This testing includes performance-enhancing drugs as well as illicit substances such as marijuana, amphetamines and cocaine. Illicit drugs are tested for on match days but not on non-match days. Some athletes are known to use illicit substances for recreational purposes, away from competition times and this poses a serious health and welfare issue not addressed by the usual sport drug testing regimes. This paper reports the results of the first 7 years of an illicit drug-testing programme that included non-match day testing in the elite Australian Football competition, the Australian Football League (AFL).

Methods Players in the AFL were tested for illicit drugs both in-competition and out-of-competition. Players were selected for illicit substance tests either randomly or targeted based on previous test history or time since previous test. The number of tests conducted was increased each year from 2005 to 2011 and testing was focused on high-risk times during non-competition periods.

Results There were no positive match day tests. There was a significant reduction in positive tests (19–6) for illicit drugs during non-competition periods over the 7 years (p<0.0001). The reduction in positive tests may be related to player education, the greater number of tests conducted and the harm minimisation approach of the illicit drug policy.

Conclusions An illicit drugs programme using a harm minimisation strategy can work effectively alongside a sport’s WADA compliant Anti-Doping Code.

INTRODUCTION
Illicit drug use for recreational purposes is a substantial issue within Western society and causes significant health issues.1 In Australia society the incidence of use of any illicit drug at least once in a lifetime has been reported to be 58% and even higher for the 20–29 age group.2 Over a 12-month period (in 2006) 11% of the population were reported to use cannabis, and 9% used amphetamines.2

The incidence of illicit substance use in elite sporting groups, based on self-report surveys, is lower than the community. Dunn et al3 reported that 7% of Australian athletes had used illicit drugs in the past year and elite Australian athletes had a 21% lifetime cannabis use, 9.5% for ecstasy and 6.7% for cocaine. These findings were similar to data from the USA; Green et al4 noted a self-report incidence of recreational drug use in National Collegiate Athletic Association (NCAA) college athletes at 28.4% for marijuana, 3.1% for amphetamine and 1.5% cocaine.

Testing individuals for drug use is uncommon in the community but practiced regularly in elite sport to detect drug use. The first stand against drug use in sport was taken by the International Amateur Athletic Federation in 1928. The anti-doping movement gained real momentum in 1967 when the International Olympic Committee released its first list of prohibited substances.5 The anti-doping movement was further facilitated by the formation of the World Anti-Doping Agency (WADA) in 1999 and the subsequent harmonisation of anti-doping policies in most sports and countries.6 Testing of sports people for drug use is now regularly conducted both in-competition and out-of-competition for performance-enhancing drugs, including testing for common illicit recreational drugs as a part of in-competition tests.

The use of performance-enhancing drugs has a clear impact on sporting competition. However, the use of illicit drugs, such as cannabis and stimulants, used recreationally, well away from competition time, are less clearly linked to enhanced sporting performance and may even be detrimental. Interestingly, the WADA Code can apply the same sanctions for the use of illicit substances for performance-enhancing effects in competition testing and inadvertent recreational use away from the competition period.5 Illicit drugs such as cannabinoids are not widely considered performance enhancing and are presumably on the list under the health risk criteria.5 7 However, the WADA Prohibited List includes cannabinoids in the in-competition testing6 but not non-competition testing when the health risks would be the same.

Alongside the health risks of illicit substance use, elite athletes also have a welfare risk because they are subject to sanctions for drug use under their sport’s anti-doping codes. Athletes risk sanctions of 2 years or more and for professional athletes such as Australian Football League (AFL) players this has a substantial impact on their welfare.

Because of the differences between substances tested for in-competition and those tested for out-of-competition under the WADA Code, and considering anecdotal reports of drug use and the advice of experts and health promotion organisations, the AFL introduced an Illicit Drugs Policy (IDP) in 2005. This policy started after extensive expert and stakeholder consultation and agreement and the support of the AFL Players Association. The new strategy was introduced to strengthen the AFL Anti-Doping Code (ADC) and close the gap in illicit substance testing by including the non-competition period.

The AFL IDP places player health and welfare as its primary goal. The policy includes League-wide
education and the first two detections are responded to with confidential athlete counselling, treatment and rehabilitation. Sanctions occur with the third detection. Since inception, the programme has evolved with increased test numbers, better test targeting and improved medical interventions after detection.

The programme runs in parallel with the WADA compliant AFL ADC that primarily targets performance-enhancing drugs and illicit substances in game day testing. This paper reports the outcomes of the first 7 years of the AFL IDP.

METHODS

Players from the 16 clubs participated in drug testing under the ADC and IDP. Each club had a playing list of approximately 40 male players (approximately 640 players), indicative mean age, height and weight of the players in the period 2005–2010 was 23 years, 188 cm and 87 kg. All players in the AFL were tested under the two drug policies on game days and at any training session during the pre-season and competition season. During the players’ holiday break (3 weeks) players return to their club once at which time they could be tested under the IDP. Immediately after the holiday break when the players have returned to training for preparation of the AFL competition there is a period of increased IDP testing.

The ADC testing examined urine specimens for both performance-enhancing drugs and recreational drugs (WADA S1–S9 and M1–M3) in competition tests and the IDP examined specimens for commonly used drugs classified under WADA as S6–S8 (cocaine, ecstasy, amphetamines, narcotics and cannabis) as well as γ-hydroxybutyric acid and ketamine.

The ADC testing was conducted by the Australian Sport Anti-Doping Authority (ASADA) and IDP testing was conducted by a commercial pathology laboratory. Random and targeted tests were conducted. Players were picked for random tests from a list of players at a training session by the testing officials. Targeted tests were directed at players with a previous history of a positive drug test and players who had not been tested in the past 12 months.

In-competition tests were conducted at the playing venue with the drug test personnel notifying the players and collecting the specimens after the game according to WADA protocols. Standard testing privacy and collection procedures were used. Non-competition testing followed similar protocols but were conducted at team training facilities.

Drug testing is part of the players’ contract with the AFL and while players did not sign informed consent, the provision of data to third parties for authorised research as overseen by club medical officers is part of the standard playing contract. This manuscript was generated out of the AFL data which is in the public domain. An exemption from ethics was obtained from Monash University, Australia.

RESULTS

There was a steady decline in the annual number of positive tests (22–6) over the 7 years of the programme. There were six illicit substance detections under the IDP testing programme during 2011 and the detection rate was 0.4% compared to 4.03% in 2005 when the programme started. There was a significant reduction in the proportion of positive tests between 2005 and 2011 (table 1, McNemars test, $\chi^2=450.4$, $p<0.0001$).

The mean age of players who had a first detection was 23.8 years (range 19–30 years, median 25 years).

The reduction in positive tests has coincided with a 350% increase in the number of tests conducted and the shift of IDP testing times to high-risk periods such as the period immediately after a game when a player was socialising or early in the postseason when players start their break from competition and training.

All detections (80) were from the IDP testing. There were no positive drug tests from the competition tests conducted under the AFL ADC. Aside from the decrease in detections, there has been a trend away from the use of cannabinoids (table 2).

The association with alcohol consumption was compelling; 56 detections were associated with alcohol use, six were not and the data on the remaining 18 was not collected in the first year of the programme. Interestingly, illicit drug use was mostly conducted away from team mates; only six detections were associated with drug use with a team mate, 65 were not and 9 were unknown.

DISCUSSION

This paper reports on detections of illicit substances in a large group of elite male Australian football players. There has been a steady decline in the number of detections in the 7 years of the IDP in the face of a substantial increase in the number of tests conducted, targeting of players and targeting of high-risk periods. Most detections occurred in the non-competition period, suggesting that illicit substance use was opportunistic, discretionary and not for any performance enhancement effects.

The results of testing over 7 years suggest that the AFL IDP is an effective programme in modifying player behaviour thereby positively impacting on the health and welfare of players. The determination of the AFL and the AFL Players Association in addressing the issue of illicit drug use by players and the commitment of the players themselves and their teams has contributed to the success of the policy.

The IDP additionally appears to have induced behavioural change in players as seen in the reduction in cannabinoid use. Cannabinoids have a long detection window of up to 6 weeks.
(compared with stimulants of 3–4 days) and out-of-competition testing reduces the opportunity to use cannabis without detection to almost zero as the players only have an 8-week break from playing or training. It appears players have responded to the greater detection risk of cannabinoids.

Most literature reporting on drug use has relied on player surveys and very little has been written about the outcomes of drug testing in other sports. Rossi et al. reported the outcomes of 95,000 ADC mostly in-competition tests (15% of tests were out-of-competition) over 9 years in elite sports participants in Italy. They demonstrated that between 1% and 1.8% of tests were positive to all prohibited substances, the incidence fluctuating over the 9 years but not trending down. They did note a high proportion of the positive tests involved stimulants and drugs of abuse and further deduced that their intake appeared not to be for performance enhancement but rather for activities not related to sport.

Illicit recreational drugs comprise a high proportion of the positive tests that arise from competition testing in WADA compliant elite sport. In Australia, WADA compliant testing across all sports is undertaken by ASADA. In a 4-year period the ASADA testing had a detection rate of 0.58% for all prohibited substances across all sports. Of this total number of ASADA tests the detection of illicit substances at in-competition tests was 0.51% or over 80% of the total. However it is not clear, except in the case of cannabinoids, whether these substances were used by athletes for potential performance-enhancing effects or for recreational purposes and therefore inadvertent from a sport performance perspective.

There is a suggestion that more testing may reduce illicit drug use and this study supports this supposition given the decrease in positive tests with greater test numbers. Professional football players in England reported widespread use of recreational drugs in an environment of low testing; only 66% had been tested in the previous 2 years and 60% felt they were unlikely to get tested that year. It would appear that more testing is likely to impact on athlete behaviour.

The operational approach of the AFL IDP includes education across the whole player group and initially confidential clinical management overseen by AFL Medical Officers for players with detections. This approach has evolved over the 7 years of the IDP with the introduction of mandatory club doctor notification and mandatory independent addiction medicine specialist assessment for players with positive tests. In the AFL IDP the results of the first two detections remain confidential between the player and clinicians. A third detection results in referral to the AFL General Manager Football Operations and an open assessment for players with positive tests. In the AFL IDP with the introduction of mandatory club doctor notification the player and clinicians. A third detection results in referral to the AFL General Manager Football Operations and an open assessment for players with positive tests. In the AFL IDP with the introduction of mandatory club doctor notification the player and clinicians. A third detection results in referral to the AFL General Manager Football Operations and an open assessment for players with positive tests. In the AFL IDP the introduction of mandatory club doctor notification and mandatory independent addiction medicine specialist assessment for players with positive tests.

Harm minimisation is an effective approach to managing illicit drug abuse alongside existing established punitive methods. These data, particularly in the case of cannabinoids, suggest that ‘performance enhancement’ can be an absolute criterion before a substance is added to the WADA Prohibited List. The inclusion of substances that are primarily harmful to health or in contravention of the spirit of sport can be dealt with by an alternative mechanism.
A strategy to reduce illicit drug use is effective in elite Australian football
