LETTERS TO THE EDITOR

The football club doctor system

EDITOR,—I read with interest the paper by Waddington et al highlighting the inadequacies of the football club doctor system in Britain. This paper confirms the situation that many people already knew to exist. Advertisements for club doctors are rarely published in medical journals, doctors normally being appointed on a “who you know” basis. It is also particularly disappointing that, at a time when any specialty of sports and exercise medicine is being established in this country, the majority of doctors working with professional footballers have no qualifications or little experience in the specialty. However, this is not confined to football clubs and probably also applies to rugby clubs and many other sporting associations.

One aspect not mentioned in the paper is medical litigation. It is to be hoped that doctors involved with football clubs have arranged defence cover, because, if a situation arises in which a player’s sporting career is threatened by medical mismanagement and the doctor involved has no professionally recognised sports medicine qualification, he or she could be found guilty of medical negligence. With the amount of money involved in professional football, this could lead to dire consequences for the doctor and the medical defence cover, because, if a local privately run sports medicine clinic was present at the hospital would you have preferred your injury to have received further treatment at this clinic rather than your local GP practice? A response rate of 47.5% was obtained, 89% would have preferred their injury to be reviewed at a sports medicine clinic. Various reasons were given for this preference, with many feeling that their GP was not interested or not the specialist qualification may be unique to that sport. We agree that there is a need to investigate all aspects of the provision of medical and physiotherapy care in other sports. In this regard, your readers may be interested to know that two of our colleagues at Leicester, Dr Ken Sheard and Dominic Malcolm, are now carrying out a similar study to our own, but in rugby union.

Sports medicine clinics on the NHS: a patient survey

EDITOR,—Following the recent success of the British team at the Sydney Olympics, media and medical attention appears to be preoccupied with the health and welfare of the “elite athlete”. However, the overwhelming majority of people who participate in sport in this country are not at an elite level. In fact, the term “athlete” may not even be correct. Many people participate in sport for the physical benefits of exercise and the personal enjoyment that it brings. When these people are acutely injured, their first port of call is their GP or local A&E department. If physiotherapy is required, there is often a lengthy waiting period. For chronic or overuse injuries, the GP may not have the time, inclination, or qualifications to deal competently with their management. The opinion of an orthopaedic consultant is desired, six months or more may elapse before an appointment. Further time will be lost in waiting for investigations and surgery. For the “ordinary” sports person, over a year may pass before they can return to their sport for an injury that may be resolved in one to two months for an “elite athlete”. Of course, if a locally privately run sports medicine clinic exists, specialist input and quicker treatment can be offered, bypassing the NHS waiting lists. But this costs money and not everyone can afford to pay.

We randomly selected 40 people who attended the A&E department with a sports injury and were discharged to the care of their GP for follow up. A questionnaire was sent to each patient asking them “if a specialist sports medicine clinic was present at the hospital would you have preferred your injury to have received further treatment at this clinic rather than your local GP practice?” A response rate of 47.5% was obtained, 94% would have preferred their injury to be reviewed at a sports medicine clinic. Various reasons were given for this preference, with many feeling that their GP was not interested or did not have the training to investigate or treat the problem correctly. Most also felt that at a sports medicine clinic they would be treated by specialists in their field similar to that of any other hospital specialty outpatient clinic. Although this survey targeted a possibly biased group, these are the majority of people with sporting injuries that we should be aiming to treat. The introduction of NHS based sports medicine clinics may be a few years away but the training of doctors to a specialist standard through regulated training schemes must start now.

New Zealand Olympic experience—Sydney 2000

EDITOR,—New Zealand’s Olympic medical team of four doctors, seven physiotherapists, one chiropractor, one massage therapist, and a sports psychologist provided medical care for a team of 150 athletes and 76 officials at the Sydney Olympic Games. During the month in Sydney, we provided 566 consultations and 1403 physiotherapy and chiropractic treatments, plus numerous massages.

All but one athlete was able to compete in their chosen event. For the athletes who required laboratory investigation or organised imaging, a comprehensive service was provided at the polyclinic within the Olympic Village. Special mention should be made of the superb organ imaging service organised by Dr Jock Anderson. Readers of the Journal may be interested to know of the rapid response to CT guided nerve root sleeve injections of corticosteroid. Three of our athletes with lumbar nerve root complaints had these injections, and all were able to compete some 48 hours after injection. This epitomises the high standard of diagnostic and therapeutic intervention that was possible, and the impressive clinical results that could be achieved.

In summary, the Olympics represent the pinnacle of sporting excellence and I am pleased to report that the medical facilities available to athletes in Sydney were of the same high standard as the achievements of the competitors.

Authors’ reply

We welcome Dr Boyce’s letter as a useful contribution to the debate generated by our article. Dr Boyce is quite correct to raise the issue of medical litigation. As the American College of Sports Medicine pointed out as long ago as 1991, what it called “the litigation epidemic” had at that time already “begun to engulf sports medicine” in the areas of negligence and malpractice, counselling, re-entry to play decisions, and other matters. It is probable that we shall in future increasingly see such cases in the United Kingdom, and the club doctor without an appropriate specialist qualification may be held to be more at risk in such cases.

Dr Boyce is also correct to draw attention to the fact that, for the past 10 years, the “crowd doctor” at professional football matches has been required to hold a recognised specialist qualification in Immediate Medical Care. The fact that club doctors are not required to hold a comparable and appropriate specialist qualification is an anomaly that needs to be addressed as a matter of priority by sports medicine authorities, by clubs, and by the Football Association. It goes without saying that he is also correct to point to the need for football clubs to adopt more realistic policies towards safeguarding their major assets, namely the health—and therefore also the playing ability—of their players.

Finally, we fully accept that, as Dr Boyce suggests, the situation that we documented in relation to professional football may not be unique to that sport. We agree that there is a need to investigate all aspects of the provision of medical and physiotherapy care in other sports. In this regard, your readers may be interested to know that two of our colleagues at Leicester, Dr Ken Sheard and Dominic Malcolm, are now carrying out a similar study to our own, but in rugby union.

Reassessing the need for sport diving medicals

EDITOR,—Dr Stephen Glen and his coauthors conclude from an analysis of medical records held by the Scottish Sub-Aqua Club (SSAC) that routine medical examination of sport divers can safely be replaced by a system of self declaration, with a questionnaire designed to indicate whether referral to a doctor with experience of diving medicine is necessary. This conclusion should be regarded as preliminary, however, because the data were not disaggregated sufficiently to reveal the additional screening value of a routine medical examination beyond that of an initial questionnaire. In addition, there are inherent statistical biases in the SSAC data that have not been addressed.

The risks associated with discontinuing routine examinations could have been investigated by quantifying the number of cases in which disqualifying conditions were found in medical examination but not declared in the prior questionnaire. However, the authors’ listing of abnormalities recorded at examination appears to include those due to conditions declared in the questionnaire. Similarly, the listing of formal referrals to approved medical referees does not indicate how many were initiated by a questionnaire response and how many as a result of an examination ending only. Crucially, the cases that were ultimately failed were not classified by type of disqualifying condition or by stage at which the condition was first detected. The prevalence of disqualifying conditions that subjects were unaware of, or otherwise did not declare, before the examination is therefore obscured.

Under the SSAC system during the study period, general practitioners could certify candidates with certain conditions as “ unfit to dive”, without referring them to a medical referee. As a certificate of fitness to dive was a prerequisite of membership of the SSAC, these subjects would not join the organisation and details of their medical examination would be unlikely to enter the medical database. The discriminatory value of medical examinations may therefore have been underestimated. It may have been rare that subjects were failed outright without a medical referee being consulted (when their details would be more likely to enter the database), but that eventuality should be considered and if possible quantified.

The data set is also biased by the inclusion of “repeat” medicals (routine periodic reexamination of divers), which comprised nearly 30% of the records analysed. This probably included some degree of pseudo-replication, but even if there was only one record for each individual, one may expect a lower prevalence of disqualifying conditions among a group who had previously been certified “ fit” than among first time applicants. The prevalence of disqualifying conditions among new applicants therefore needs to be estimated separately.

The authors may be correct that routine medical examinations for sport diving are unnecessary, but if policy on such an important safety issue is to be changed, the justification for doing so should be clearly demonstrated and qualified according to the limitations of the available data.

Authors’ reply

The main conclusions of our paper were that no significant unexpected abnormalities were found on clinical examination of divers in the Scottish Sub-Aqua Club, and that the questionnaire was the important part of the screening assessment of divers. This remains the case regardless of how the information is analysed.

In response to the questions raised by Philip Smith, only 391 divers responded “No” to all questions, and none had abnormalities on clinical examination. All of the referrals to medical referees were prompted by positive questionnaire responses, and the divers were assessed by doctors with diving medicine experience. The interim step of clinical examination by a doctor without such experience did not alter the outcome.

Divers start training with the SSAC by undergoing basic snorkel and rescue training (as with most diving organisations) and may progress to scuba training after a medical examination. They entered the SSAC system during the snorkel training, however, and in our experience GPs did not fail divers outright before contacting SSAC headquar ters or a medical referee. It is not possible to confirm that all divers were referred in this way, but it is reassuring that an analysis of the medical forms after the introduction of a self certifying system has confirmed an increase in the number of divers failing on the basis of questionnaire responses alone.

It was necessary to include the repeat medicals in the analysis because the introduction of a new system must be effective in the existing divers as it is in the new entrants. Confirm that all divers may develop in the period between medicals, which can be up to five years. Removing the repeat medicals from the analysis does not affect the final conclusion, but it confirms that the questionn aire is the most important part of the screening process.

A new questionnaire system was introduced in March 2000 and analysis of the short term screening has shown a slight increase in the number of divers failing their medical assessment. A complete report will be submitted for publication shortly. In addition, all forms submitted by divers are now reviewed by diving doctors, and assessment is only performed by doctors with diving medicine experience. This helps to ensure a consistent application of the medical standards recommended by the UK Sport Diving Medical Committee. There has been no change in the incident pattern although it is too early to expect major differences to become apparent.

It is worth noting that the role of routine medical examinations has been questioned elsewhere, and that the number of diving accidents related to medical conditions did not significantly change when compulsory medicals were introduced in Australia and New Zealand. The problem in assessing fitness to dive has been the fact that divers have been assessed by doctors without diving medicine experience, and the introduction of the new system has allowed this to be rectified. Divers should not be falsely reassured by the value of a screening medical examination performed by a doctor without diving medicine experience.

Management of diabetes at high altitude

EDITOR,—In response to the leader of Moore et al., we would like to report the results obtained in eight type I diabetic mountaineers who ascended the Aconcagua (6950 m) without any significant medical problems. The only climber unable to make the summit, because of a problem not related to diabetes, reached 6700 m.

None of the climbers took any drugs to prevent acute mountain sickness (AMS) because of the possible risks. Instead, they acclimatised gradually. Above 5000 m some of the diabetic climbers experienced hypoglycaemia after dinner with nocturnal hyperglycaemia probably because of delayed absorption of carbohydrates, and at altitude and rapid absorption of the Lispro Insulin used by most of the group. We recommended delaying the administration of insulin until the end of dinner.

There were no problems with glucometers. The devices were protected with home made bags and carried next to the skin.

As expected, all members of the team suffered bouts of hypoglycaemia and hyperglycaemia but were managed successfully. Glycaemia was monitored on average seven times a day. The expedition doctor had to intervene in only one case of medium postprandial hyperglycaemia at 5000 m. In a previous investigation of type I diabetic climbers, 15 out of 24 of the climbers reached altitudes above 5000 m (three above 7000 m). None reported major complications at altitude nor taking any drugs to prevent AMS. In climbers under 3000 m, hyperglycaemia caused by dehydration (two cases) or extensive sunburn (one case) were reported; all were self managed and resolved before the climbers reached hospital. One climber had previously measured his glycaemia at a height of 8200 m on Mount Everest. He tested the glucometer in the hypobaric chamber at 5000 m without any significant differences from sea level.

Optimal management of the diabetes, together with progressive acclimatisation, was the key to success. All the team were good at self monitoring under any conditions and had the skill to calculate insulin and carbohydrates and the ability to handle early hyperglycaemia and hypoglycaemia.

Climbing mountains at high altitude is a risky sport. Diabetic climbers should not be deterred from going to altitude provided that they are aware of the increased risks and the importance of frequent self monitoring and gradual acclimatisation to avoid AMS.

The future for the field of sports medicine

EDITOR.—Can I begin by expressing my appreciation for the introductory free access to the journal since its launch on the web earlier this year.

This year I have undertaken an intercalated degree in clinical medicine which has been offered by the Department of Medicine and Therapeutics at Glasgow University for the past four years. Over 60 of my fellow students opted to do the same. We each, however, opt to do a specialist module in addition to a common core course. The options include cardiovascular studies, clinical neuroscience, and cancer studies for among others. I chose to do sports medicine, largely because of my own interest and participation in sport. Indeed participation in sport was a common factor among the 10 students opting for this module. Admittedly many of us felt that this, compared with some of the other modules, would not be a particularly taxing option. Our reputation as “slackers” among the rest of the year group was evident. As far as they were concerned, we were focused in front of the whiteboards grappling with the serious issues at the cutting edge of medical research! However, although I have thoroughly enjoyed the lectures, this was by no means the easy option, and I agree wholeheartedly with Paul McCrory that it is about time attitudes changed.

Who says there are no serious issues in this field? Consider the dilemma of the physician who has been phlebotomised to give a pain killing injection to a young player, with the risk national scout will be at this match and this is his only chance to make an impression. Consider the responsibility, swift judgment, and strength of character that may be his only chance to make an impression. Consider also the responsibility, swift judgment, and strength of character required when faced with the head injured player who knows he will be out for a whole season if he comes off, and then of course there’s his coach...

The elite athlete has emerged as someone with specialist medical needs, and we need specialist sports medicine physicians to respond.

But then the field of sports medicine goes far beyond these more traditional roles into a wide range of other specialties: cardiology, respiratory medicine, gynaecology, rheumatology, neurology, to name but a few of the areas our tutors have explored. We need specialists who can advise in each of these areas, but to whom can they turn for a more well conducted approach, to provide physical therapists with the necessary evidence base.

What has been most evident throughout is the requirement for more well conducted research and clinical guidelines based in this field. We are a generation of medical students for whom the term evidence based medicine (EBM) is used more frequently than coronary heart disease (CHD). My fellow students this year are involved in researching areas as diverse as the thrombolytic response and contrasting platelet activity during exercise (surprisingly there are still no definitive answers here), the role of strength training in rheumatoid arthritis, the relation between knee injuries in female footballers and the menstrual cycle, the barriers to exercise in cardiac rehabilitation patients, and many but a few.

I may only be at the beginning of my medical career but I feel I have had a valuable impression into the challenge and diversity presented by this field. It has great potential it holds, and I look forward to changed attitudes and a more formal recognition of this specialty.

Height of Kilimanjaro

EDITOR.—As one who, for my running exploits on Kilimanjaro, was mentioned in Damian Bailey’s excellent letter on high altitude mountaineering, may I correct an error in the paper by Moore et al in the same issue of this journal? They give the height of Kilimanjaro as 4593 m (14 960 ft). However, the surveyed height of Uhuru Peak on the Kibo summit of Kilimanjaro is 5895 m or 19 340 ft, and believe me, it always felt like it!

BOOK REVIEW

This clinical companion is a reference text for physiotherapists, which attempts to cover all aspects of clinical care as encountered by this clinical group. It has a strong American bias and aims, using a broad based clinical approach, to provide physical therapists with relevant information so that they have a thorough understanding of patients’ conditions.

My first impression of this book is that it is compact and well structured with an interesting and diverse contents list. Information is easily accessed from its 15 chapters, which focus mainly on assessment, measurement, and rehabilitation, with a clear description of the contents of each section.

The format is logical and easy to read with an abundance of diagrams and illustrations. However, at some points in the book, the charts appear infinite and interrupt the text for longer than my concentration would allow. The book fulfills the readers’ demand to browse through the pages for light reading, but, although the extensive topic content is impressive, the detail is disappointing.

My interest in the book was in the musculoskeletal content which proved lacking. Common disorders encountered in an outpatient setting accounted for one third of one chapter, and the treatment it recommends for low back pain and manual handling manoeuvres would not be keeping with current clinical effectiveness guidelines in the United Kingdom. Other areas covering diagnostic tests, signs and symptoms, and outcome measures are covered succinctly for physiotherapists.
The text fulfils its role as a quick reference guide for junior staff or students; however, it is a little overambitious in its diversity and is non-specific in relation to relevant physiotherapy practice.

**Australia recognises sports physicians**

The Australian government’s Health Insurance Commission (HIC) has granted sports physicians with a Fellowship of the Australian College of Sports Physicians access to their own Medicare item numbers. This recognises sports physicians as a separate entity from general practitioners and restores their rebate to the equivalent of a vocationally trained GP. This is the first time the HIC has recognised a “special group” and is a significant step forward in the quest for full specialist recognition. This process is about to resume now that the Australian Medical Council has established a new process for recognition of new specialties.
