LETTERS TO THE EDITOR

The football club doctor system

EDITOR,—I read with interest the paper by Waddington et al highlighting the inadequacies of the football club doctor system in Britain. This paper confirms the situation that many people already knew to exist. Advertisements for club doctors are rarely published in medical journals, doctors normally being appointed on a “who you know” basis. It is also particularly disappointing that at a time when any specialty of sport and exercise medicine is being established in this country, the majority of doctors working with professional footballers have no qualifications or little experience in the specialty. However, the entry to football clubs and probably also applies to rugby clubs and many other sporting associations.

One aspect not mentioned in the paper is medical litigation. It is to be hoped that doctors involved with football clubs have arranged medical defence cover, because, if a situation arises in which a player’s sporting career is threatened by medical management and the doctor involved has no professionally recognised sports medicine qualification, he or she could be found guilty of medical negligence. With the amount of money involved in professional football, this could lead to dire consequences for the medical career of the practitioner involved.

From a report commissioned by the Football League on the Hillsborough tragedy, the concept of the “crowd doctor” was introduced, meaning that any doctor involved in the medical care of the crowd at a football stadium would be required to possess at least the Diploma in Immediate Medical Care. Before that, the situation was similar to that of the present club doctor system, and few doctors held any recognisable qualifications or training in medical emergencies and resuscitation.

A similar recommendation by sports medicine authorities is required to enhance the quality of service provided to football clubs and increase the stature of the specialty. However, it is not a one sided situation. Football clubs must realise the benefits of exercise and the personal enjoyment people participate in sport for the physical term “athlete” may not even be correct. Many country are not at an elite level. In fact, the British team at the Sydney Olympics, media reports, and the superb organ imaging service organised on October 29, 2023 by guest. Reassessing the need for sport diving medicals

EDITOR,—Dr Stephen Glen and his coauthors conclude from an analysis of medical records held by the Scottish Sub-Aqua Club (SSAC) that routine medical examination of sport divers can safely be replaced by a system of self declaration, with a questionnaire designed to indicate whether referral to a doctor with experience of diving medicine is necessary. They conclude that such a system would be more likely to reveal the additional screening value of a routine medical examination beyond that of an initial questionnaire. In addition, there are inherent statistical biases in the SSAC data that have not been addressed.

The risks associated with discontinuing routine examinations could have been investigated by quantifying the number of cases in which disqualifying conditions were found in medical examination but not declared in the prior questionnaire. However, the authors’ listing of abnormalities recorded at examination apparently includes those due to conditions declared in the questionnaire. Similarly, the listing of formal referrals to approved medical referees does not indicate how many were initiated by a questionnaire response and how many as a result of an examination ending only. Crucially, the cases that were ultimately failed were not classified by type of disqualifying condition or by stage at which the condition was first detected. The prevalence of disqualifying conditions among new applicants therefore needs to be estimated separately. The prevalence of disqualifying conditions that subjects were unaware of, or otherwise did not declare, before the examination is therefore obscured.

Under the SSAC system during the study period, general practitioners could certify candidates with certain conditions as “ unfit to dive” , without referring them to a medical referee. As a certificate of fitness to dive was a prerequisite of membership of the SSAC, these subjects would not join the organisation and details of their medical examination would be unlikely to enter the medical database. The discriminatory value of medical examinations may therefore have been under-estimated. It may have been rare that subjects were failed outright without a medical referee being consulted (when their details would be more likely to enter the database), but that eventuality should be considered and possibly quantified.

The data set is also biased by the inclusion of “repeat” medicals (routine periodic re-examination of divers), which comprised nearly 50% of the records analysed. This probably involved some degree of pseudo-replication, but even if there was only one record per individual, one may expect a lower prevalence of disqualifying conditions among a group who had previously been certified “fit” than among first time applicants. The prevalence of disqualifying conditions among new applicants therefore needs to be estimated separately.

The authors may be correct that routine medical examinations for sport diving are unnecessary, but if policy on such an important safety issue is to be changed, the justification for doing so should be clearly demonstrated and qualified according to the limitations of the available data.

Authors’ reply

The main conclusions of our paper were that no significant unexpected abnormalities were found on clinical examination of divers in the Scottish Sub-Aqua Club, and that the questionnaire was the important part of the screening assessment of divers. This remains the case regardless of how the information is analysed.

In response to the questions raised by Philip Smith, only 391 divers responded “No” to all questions, and none had abnormalities on clinical examination. All of the referrals to medical referees were prompted by positive questionnaire responses, and the divers were assessed by doctors with diving medicine experience. The interim step of clinical examination by a doctor without such experience does not alter the final outcome.

Divers start training with the SSAC by undergoing basic snorkel and rescue training (as with most diving organisations) and may progress to scuba training after a medical examination. They entered the SSAC system during the snorkel training, however, and in our experience GPs did not fail divers outright before contacting SSAC headquarters or a medical referee. It is not possible to confirm that all divers were referred in this way, but it is reassuring that an analysis of the medical forms after the introduction of a self certifying system has confirmed an increase in the number of divers failing on the basis of questionnaire responses alone.

It was necessary to include the repeat medicals in the analysis because the introduction of a new system must be as effective in the existing divers as it is in the new entrants. New medical conditions may develop in the period between medicals, which can be up to five years. Removing the repeat medicals from the analysis does not affect the final conclusion, but it confirms that the questionnaire is the most important part of the screening process.

A new questionnaire system was introduced in March 2000 and analysis of the short term success has shown a slight increase in the number of divers failing their medical assessment. A complete report will be submitted for publication shortly. In addition, all forms submitted by divers are now reviewed by diving doctors, and assessment is only performed by doctors with diving medicine experience. This helps to ensure a consistent application of the medical standards recommended by the UK Sport Diving Medical Committee. There has been no change in the incident pattern although it is too early to expect major differences to become apparent.

It is worth noting that the role of routine medical examinations has been questioned elsewhere, and that the number of diving accidents related to medical conditions did not significantly change when compulsory medicals were introduced in Australia and New Zealand.1 The main problem in assessing fitness to dive has been the fact that divers have been assessed by doctors without diving medicine experience, and the introduction of the new system has allowed this to be rectified. Divers should not be falsely reassured by the value of a screening medical examination performed by a doctor without diving medicine experience.

Management of diabetes at high altitude

EDITOR,—In response to the leader of Moore et al., we would like to report the results obtained in eight type 1 diabetic mountain climbers who ascended the Aconcagua (6950 m) without any significant medical problems. The only climber unable to make the summit, because of a problem not related to diabetes, reached 6700 m.

None of the climbers took any drugs to prevent acute mountain sickness (AMS) because of the possible risks. Instead, they acclimatized gradually.

Above 5000 m some of the diabetic climbers experienced hypoglycaemia after dinner with nocturnal hyperglycaemia probably because of delayed absorption of glucose at altitude and rapid absorption of the Lispro Insulin used by most of the group. We recommended delaying the administration of insulin until the end of dinner.

There were no problems with glucometers. The devices were protected with home made bags and carried next to the skin.

As expected, all members of the team suffered bouts of hypoglycaemia and hyperglycaemia but were managed successfully. Glycaemia was monitored on average seven times a day. The expedition doctor had to intervene in only one case of mild postprandial hypoglycaemia at 5000 m.

In a previous investigation of type 1 diabetic climbers, 15 out of 24 of the climbers reached altitudes above 5000 m (three above 7000 m). None reported major complications at altitude nor taking any drugs to prevent AMS. In climbs under 3000 m, hypoglycaemia caused by dehydration (two cases) or extensive sunburn (one case) were reported; all were self managed and resolved before the climbers reached hospital. One climber had previously measured his glycaemia at a height of 8200 m on Mount Everest. He tested the glucometer in the hypobaric chamber at 5000 m without any significant differences from sea level.

Optimal management of the diabetes, together with progressive acclimatisation, was the key to success. All the team were good at self monitoring under any conditions and had the skill to calculate insulin and carbohydrates and the ability to handle early hyperglycaemia and hypoglycaemia.

Climbing mountains at high altitude is a risky sport. Diabetic climbers should not be deterred from going to altitude provided that they are aware of the increased risks and the importance of frequent self monitoring and gradual acclimatisation to avoid AMS.

Sports doctors’ resuscitation skills under examination—additional facts

EDITOR,—Further to the recent article Sports doctors’ resuscitation skills under examination—which they take it seriously? there are some additional facts that support the argument.

The University of Bath diploma course in sports medicine for doctors includes teaching material on life support and spinal management. The relevant section of the primary care module workbook, edited by Lavis and Rose, contains a full description of resuscitation and spinal management. The tutor marked assignments that indicate the completion of the primary care module require description of the application of these skills to a defined situation. The residential component of the course, designed to rehearse practical skills, includes three hours of first aid revision and training conducted by one or more of the article authors.

The failure rate in the examination of proficiency in basic life support and spinal management of a potential spinal injury is in marked contrast with that of the other components of the course where a reasonable pass rate is obtained.

It does therefore seem possible that the reported failure rate is not due to the inadequacy of the teaching material, rather a perception by doctors that resuscitation and life support are not relevant to their work. The article reports other studies that highlight the poor standards of doctors in these skills. It cannot be assumed that doctors entering a sports medicine teaching course have previously acquired proficiency in the skills of resuscitation and the management of potential spinal injury.

It does suggest that there is an urgent need to educate doctors in their responsibility, not only to the community as a whole but also to the at higher risk sporting population, to be proficient in life saving skills. The widely reported court case in which the boxer Michael Watson successfully claimed damages for personal injuries sustained in a boxing match—his coach was present, but did not intervene—drew the comment from the judge that he had heard nothing to suggest that the doctors at the ringside were chosen because of their specialisation.

requirement for an annual practical appraisal of the lifesaving skills of doctors involved in the everyday care of patients may not be inappropriate.

The future for the field of sports medicine

EDITOR,—Can I begin by expressing my appreciation for the introductory free access to the journal since its launch on the web earlier this year.

This year I have undertaken a part-timulated degree in clinical medicine which has been offered by the Department of Medicine and Therapeutics at Glasgow University for the past four years. Over 60 of my fellow students opted to do the same. We each, however, opt to do a specialist module in addition to a common core course. The options include cardiovascular studies, clinical neuroscience, and cancer studies for among others. I chose to do sports medicine, largely because of my own interest and participation in sport. Indeed participation in sport was a common factor among the 10 students opting for this module.

Admittedly many of us felt that this, compared with some of the other modules, would not be a particularly taxing option. Our reputation as “slackers” among the rest of the year group was evident. As far as they were concerned we were not prepared in fun things while they grappled with the serious issues at the cutting edge of medical research! However, although I have thoroughly enjoyed the lectures, this was by no means the easy option, and I agree wholeheartedly with Paul McCrory that it is about time attitudes changed.

Who says there are no serious issues in this field? Consider the dilemma of the physician who has been pleaded to give a pain killing injection to a young player, with the risk of more serious damage, because an international will be at this match and this may be his only chance to make an impression. Consider also the responsibility, swift judgment, and strength of character required when faced with the head injured player who knows he will be out for a whole season if he comes off, and then of course there’s his coach . . .

The elite athlete has emerged as someone with specialist medical needs, and we need specialist sports medicine physicians to respond.

But then the field of sports medicine goes far beyond these more traditional roles into a wide range of other specialties: cardiology, respiratory medicine, gynaecology, rheumatology, neurology, toxicology, to name but a few of the areas our lecturers have explored. We need specialists who can advise in each of these areas, but to enable them to do so we need to provide them with the necessary evidence base.

What has been most evident throughout is the requirement for more well conducted research and clinical guidelines based in this field. We are a generation of medical students for whom the term evidence based medicine (EBM) is used in as many ways as coronary heart disease (CHD). My fellow students this year are involved in researching areas as diverse as the thrombolytic response and contrasting platelet activity during exercise (surprisingly there are still no definitive answers here), the role of strength training in rheumatoid arthritis, the relationship between knee injuries in female footballers and the menstrual cycle, the barriers to exercise in cardiac rehabilitation patients, and much more.

I may only be at the beginning of my medical career but I feel I have had a valuable insight into the challenge and diversity presented by this field, which holds great potential it holds, and I look forward to changed attitudes and a more formal recognition of this specialty.

Height of Kilimanjaro

EDITOR,—As one who, for my running exploits on Kilimanjaro, was mentioned in Damian Bailey’s excellent letter on high altitude mountaineering, may I correct an error in the paper by Moore et al in the same issue of this journal? They give the height of Kilimanjaro as 4593 m (14 960 ft). However, the surveyed height of Uhuru Peak on the Kibo summit of Kilimanjaro is 5895 m or 19 340 ft, and believe me, it always felt like it!

BOOK REVIEW

Physical therapist’s clinical companion.

This clinical companion is a reference text for physiotherapists, which attempts to cover all aspects of clinical care as encountered by this clinical group. It has a strong American bias and aims, using a broad based clinical approach, to provide physical therapists with relevant information so that they have a thorough understanding of patients' conditions.

My first impression of this book is that it is compact and well structured with an interesting and diverse contents list. Information is easily accessed from its 15 chapters, which focus mainly on assessment, measurement, and rehabilitation, with a clear description of the contents of each section.

The format is logical and easy to read with an abundance of diagrams and illustrations. However, at some points in the book, the charts appear infinite and interrupt the text for longer than my concentration would allow. The book simulates the reader to browse through the pages for light reading, but, although the extensive topic content is impressive, the detail is disappointing.

My interest in the book was in the musculoskeletal and extreme altitude mountaineering which proved lacking. Common disorders encountered in an outpatient setting accounted for one third of one chapter, and the treatment it recommends for low back pain and manual handling manoeuvres would not be a particularly taxing option. Also, keeping with current clinical effectiveness guidelines in the United Kingdom.

Other areas covering diagnostic tests, signs and symptoms, and outcome measures are covered succinctly for physiotherapists.

LA<br>www.bjportmed.com
The text fulfils its role as a quick reference guide for junior staff or students; however, it is a little overambitious in its diversity and is non-specific in relation to relevant physiotherapy practice.

Australia recognises sports physicians

The Australian government’s Health Insurance Commission (HIC) has granted sports physicians a Fellowship of the Australian College of Sports Physicians access to their own Medicare item numbers. This recognises sports physicians as a separate entity from general practitioners and restores their rebate to the equivalent of a vocationally trained GP. This is the first time the HIC has recognised a “special group” and is a significant step forward in the quest for full specialist recognition. This process is about to resume now that the Australian Medical Council has established a new process for recognition of new specialties.
