Rapid responses

If you have a burning desire to respond to a paper published in Br J Sports Med, why not make use of our “rapid response” option?

Union to our website (www.bjsportmed.com), find the paper that interests you, click on “full text” and send your response by email by clicking on “letters submit a response”.

Providing it isn’t libellous or obscene, it will be posted within seven days. You can retrieve it by clicking on “read letters” on our homepage.

The editors will decide, as before, whether to also publish it in a future paper issue.

Rehabilitation of lumbar multifidus dysfunction in low back pain: strengthening versus a motor re-education model

Regarding the article “Effects of three different training modalities on the cross sectional area of the lumbar multifidus in patients with chronic low back pain,” I would like to extend my appreciation to Dr Danneels and his colleagues for their interest in contributing to the literature on this important and clinically relevant topic. Unfortunately, there are important design and methodological flaws inherent in this study which call into question its results and primary conclusions. I respectfully submit this review of the study, its findings, and the authors’ clinical recommendations.

The objective of the investigation of Danneels et al was to determine the potential for different exercise models to reverse the pathology related atrophy of the lumbar multifidus muscle in people with low back pain. As described by various researchers, the lumbar multifidus experiences a number of morphological and neurophysiological changes following low back injury. One of these changes is a segmental atrophy which develops at the level of pathology, on the symptomatic side and as quickly as 24 hours after the injury. Further, these changes have been shown to persist beyond the resolution of symptoms, and for at least five years after surgical intervention for intervertebral disc herniation. There is evidence that such findings are indicative of a neurologically mediated process rather than a simple disuse or weakness phenomenon.

In their study, Danneels and colleagues compared the motor re-education model, originally developed by Richardson et al and as studied by O’Sullivan and colleagues, against two variations of a traditional strengthening model. The first of these strength training variations utilised typical concentric and eccentric lumbar extensor loading motions. The other added a static or isometric component which was to be maintained between the concentric and eccentric phases of the exercise.

The authors concluded that, in order to correct the atrophy observed in the lumbar multifidus, patients should be engaged in strengthening exercises targeting the lumbar extensors, ideally incorporating an isometric “pause” into these exercises. Danneels et al reported that this was the only exercise model tested that developed sufficient hypertrophy to correct the multifidus atrophy seen in their experimental population. These findings conflict with those of Hides and colleagues, who have published data showing correction of the pathology-induced lumbar multifidus atrophy using a considerably more specific and subtle activation of the multifidus muscle.

Unfortunately, the method by which the authors measured the cross sectional area (CSA) of the multifidus muscle introduced a large degree of methodological error, calling into question the study’s findings. The authors’ clinical recommendations. Using computed tomography scanning, Danneels et al took measurements from three arbitrary levels of the lumbar spine (the L3 superior end plate, the L4 superior end plate, and the L4 inferior end plate) recording the CSA of the multifidus muscle at each of these levels bilaterally. They then summed the right and left multifidus CSA at each of these segments resulting in a single multifidus score for each level.

In preselecting the levels from which CSA measurements would be taken, it is possible, indeed even likely, that the pathological level would have been missed entirely in at least some of the subjects. This is important because previous studies have shown that the multifidus muscle experiences its greatest loss of CSA at the primary level of pathology. Also problematic was the decision to sum the CSA scores at each of the preselected levels. A number of studies have shown that the lumbar multifidus, ipsilateral to the pathological side experiences a cascade of neuro-morphological changes, including atrophy, in the presence of both acute and chronic pathology; whereas the multifidus contralateral to the pathological side experiences no such changes.

Taken together, the preselection of measurement levels and the summation of the bilateral multifidus CSA would have had the effect of attenuating any side to side differences in multifidus CSA even if a subject’s level of pathology happened to coincide with one of the levels from which measurements were obtained. Through either of these mechanisms, this measurement scheme would have introduced a substantial mass of healthy, non-motor dysfunctional muscle into each of the multifidus CSA measurements. The net effect of the measurement approach employed by Danneels et al, although probably intended to more discretely reflect the pathological side multifidus, was to introduce the opposite bias to the experimental intervention toward an exercise model with the ability to cause hypertrophy in healthy muscle—that is, a strengthening exercise. It is likely that the “dynamic-static” exercise recommended by the authors as being most effective for correcting the pathological atrophy of the multifidus instead caused hypertrophy of the non-pathological, non-atrophied multifidus muscle segments included in the three measurement scores. Ultimately, the study’s recommendations are unsupportable given this flaw in methodology.

The low load multifidus activation exercise, developed by Richardson et al and used by O’Sullivan and colleagues, is to be performed as a co-contraction with the transversus abdominis muscle, and is intended to correct a neurologically mediated loss of normal multifidus muscle volume, not unlike that seen in the vastus medialis following trauma or surgery involving the knee joint. In studies in which the CSA of a pathological multifidus muscle has been compared with its contra-lateral and “healthy” segmental partner, this form of motor re-education exercise has been shown to normalise the CSA of the pathological multifidus in as little as four weeks.

It is critical that both researchers and clinicians appreciate that a significant body of research now shows that the “atrophy” seen in the multifidus muscle in people with low back dysfunction is representative of a form of impaired motor control, not simple disuse weakness. As such, traditional strengthening exercises will often fail to correct this fault, just as daily physical activities fail to maintain a normal segmental CSA at the pathological level. Certainly, the historical lack of success of the rehabilitation and medical professions in treating low back pain using the variety of strength based clinical models used over the last 50 years should serve as sufficient motivation to look to more evidence based models as an explanation for the condition. The motor control dysfunction model as developed over the past decade by a variety of researchers holds great promise, both as a basis for understanding the causes of back pain and in developing effective treatment strategies for our patients.

The event side doctor: the role of the orthopaedic surgeon
Orthopaedic surgeons have long had a close association with sport. International sports players have similarly gone on to careers in orthopaedic surgery, examples being Jonathan Webb and JPR Williams.

While finding appropriate medical personnel to care for the needs of spectators and athletes at major sporting events is a challenge,1 event organisers have required the skills of volunteer orthopaedic surgeons. Many were trained as a competitive surgeon for the XVII Commonwealth Games in Manchester. As a specialist registrar in orthopaedics, and previously an emergency medicine registrar, I felt suitably skilled to be an event side doctor for the time trial, mountain biking, and road race events.

During the course of the events, I reviewed cyclists with dyspepsia and back spine spasms. I also reviewed a cameraman with hay fever and one with eye irritation possibly caused by an insect bite or allergy. Regarding true “orthopaedic bone problems”, a mountain biker presented with carpal injury, query fracture, and a mountain biking spectator with a fractured clavicle. With no x-ray facilities at the event centre, all I could do was provide immobilisation, ice treatment, analgesia, and reassurance, before referring on to a facility to provide definitive diagnosis and treatment.

Although I had a very enjoyable Games and gained greatly from the experience, I felt a little inexperienced in event side medical problems and that my occupational skills were under used because of event side facilities. The event side medical centre had adequate first aid and resuscitation equipment. Most problems could be treated by paramedics, a physiotherapist and a general practitioner trained in sports medicine.

Volunteers should appreciate that the event side doctor needs to have general rather than specialist skills. My position as an orthopaedic registrar clearly lies in the hospital setting with X-ray facilities and an operating theatre. I have not, however, been discouraged from volunteering for future events.

M Carmont

Increased endothelin-1 levels in athletes
Endothelin-1 (ET-1), a potential vasoconstrictor peptide, may contribute to the exercise-induced redistribution of blood flow in muscles.1 2 On the other hand, the latter parameter in athletes may be expanded secondarily to muscle volume and as a consequence of increased ET-1 production.3 In this study, we found a difference in basal serum ET-1 levels between trained male athletes and normal matched male controls.

We studied 13 male professional football players (mean (SEM) 27 (2) years, 172 (2.5) cm, 74 (2.4) kg/m2) and 17 sedentary controls (mean (SEM) 21 (1) years, 170 (2) cm, 65 (2) kg/m2). Serum creatine kinase was also found to be significantly higher in athletes than controls subjects (22.16 (0.87) v 7.74 (0.29) pg/ml, p<0.001; values are mean (SEM)). Serum creatine kinase was also found to be significantly higher in athletes than controls (311.84 (43.3) v 110.35 (17.3) U/L, p<0.001; values are mean (SEM)).

The increased creatine kinase levels may be attributed to the increased muscle mass in athletes, and the increased serum ET-1 levels can be explained as a consequence of a widening of the vascular bed resulting from the increased muscle weight and size.

Interested in Sports Medicine?
Gain a higher degree from Australia’s leading university
The Centre for Sports Medicine Research and Education is a multidisciplinary Centre located in the Faculty of Medicine, Dentistry and Health Sciences at the University of Melbourne, Australia. It combines world-class researchers and clinicians working in the area of sports medicine.

Research Higher Degrees
The Centre offers Doctor of Philosophy (PhD), Master of Sports Medicine, Master of Physiotherapy, Master of Science, and Doctor of Medicine degrees. These are available to graduates of health and medical science courses such as physical therapy, medicine, and human movement.

Educational programme
The Centre offers a one month full time Postgraduate Certificate in Sports Physiotherapy: spine, pelvis, and lower limb. Instructors are leading clinical experts and researchers in the multidisciplinary approach to sports medicine. The Certificate will run from Nov 4–29 in 2002.

Please contact: Professor Peter Brukner: p.brukner@unimelb.edu.au (Research Degrees), Professor Kim Bennell: k.bennell@unimelb.edu.au (Research Degrees), Mr Henry Wajswelner: h.wajswelner@unimelb.edu.au (Certificate Courses), www.physioth.unimelb.edu.au/csmre
Sports medicine at the University of New South Wales
Masters of Sports Medicine
You don’t have to leave your practice:
• Delivery by distance education
• Videos, CD-ROMs and online learning
• All aspects of Sports Medicine covered
• Locally organised examinations
• Clinical training
• Certificate and Diploma courses also offered

Study Sports Physiotherapy in Australia’s sporting capital at The University of Melbourne
Qualified physiotherapists may now apply for the Master of Physiotherapy by Coursework (Sports Physiotherapy), the Postgraduate Certificate in Physiotherapy (Sports Physiotherapy of the Spine, Pelvis and Lower Limb) or the Postgraduate Certificate in Physiotherapy (Sports Physiotherapy of the Spine, Shoulder and Upper Limb). The School of Physiotherapy at the University of Melbourne now has approval for these courses and applications are open to international students for full time study.

• Applications for the Master of Physiotherapy by Coursework (Sports Physiotherapy) close 1 October 2002.
• Applications for the Postgraduate Certificate in Physiotherapy (Sports Physiotherapy of the Spine, Pelvis and Lower Limb) close 1 November 2002.
• Applications for the Postgraduate Certificate in Physiotherapy (Sports Physiotherapy of the Spine, Shoulder and Upper Limb) close 1 April 2003.

Please check the website for updates and information about the courses: www.physioth.unimelb.edu.au/postgrad.html
