ABSTRACT
Ankle injuries are a huge medical and socioeconomic problem. Many people have a traumatic injury of the ankle, most of which are a result of sports. Total costs of treatment and work absenteeism due to ankle injuries are high. The prevention of recurrences can result in large savings on medical costs. A multidisciplinary clinical practice guideline was developed with the aim to prevent further health impairment of patients with acute lateral ankle ligament injuries by giving recommendations with respect to improved diagnostic and therapeutic opportunities. The recommendations are based on evidence from published scientific research, which was extensively discussed by the guideline committee. This clinical guideline is helpful for healthcare providers who are involved in the management of patients with ankle injuries.

INTRODUCTION
In the Netherlands, about 520 000 persons annually have a traumatic injury of the ankle of which about 200 000 are a result of sports.1 Around half of the injuries receive medical treatment and 40% results in chronic instability.1 The average work absenteeism of patients with a functional-treated ligament rupture is two and a half weeks and after six weeks, 90% has returned to work.2 Of the patients who perform sports, around 60–90% resume sports after 12 weeks at the same level as before the trauma.1 About one-third of the total costs due to sport injuries are caused by ankle injuries.3 The prevention of recurrence can result in substantial cost savings. An example from a Dutch study showed mean total costs of one ankle sprain to be about €360.3 With the above-mentioned 520 000 persons with an ankle sprain, Dutch annual sports-related ankle sprain costs can roughly be estimated at €187.2 million. Productivity loss due to absence from paid and unpaid work was responsible for up to 80% of these costs.3

Despite the growing body of evidence, international debate shows controversy for best treatment strategies after ankle injuries.4 Till date, no international guidelines have been published for the management of acute ankle injuries (International Guideline Library [www.g-i-n.net]; US National Guideline Clearinghouse [www.guideline.gov]).

Recently, in the Netherlands, a clinical guideline for acute lateral ankle ligament injury was developed under the auspices of the Royal Dutch Society for Physical Therapy in cooperation with many medical professional associations and patients, following the AGREE criteria.6 Specific goal of this clinical guideline is the prevention of further health impairment of patients (ie, recurrences) by providing recommendations for improved diagnostic and therapeutic opportunities. Other goals are to obtain uniformity of diagnostics, treatment and guidance of doctors and physical therapists and other involved professional groups and to define the framework within which the multidisciplinary care of patients with ankle injuries has to take place. This guideline will also contribute to improved communication between healthcare professionals.

MATERIALS AND METHODS
The recommendations set in this guideline are, if available, based on evidence from published scientific research. Relevant articles were searched in the Cochrane Library, Medline and Embase. The full search strategy is available upon request. The language was limited to Dutch, English, German, French, Danish, Norwegian and Swedish. In search for additional information, all reference lists of the included articles were checked manually. Articles published between January 1996 and March 2009 were enclosed. The quality of included articles was assessed by epidemiologists on the basis of ‘evidence-based guideline development’ – assessment forms and classified in various levels in order of probabilistic and scientific value (tables 1 and 2). The results based on the evidence from literature are presented in categories with levels of evidence of the conclusions included. In formulating the final recommendations, the guideline committee also took other aspects into account, such as potential harm of the interventions, patients’ perspective, costs and organisational aspects. If the guideline committee decided that based on current evidence a positive recommendation was not opportune, this was stated as well. So, recommendations were evidence-based and consensus-based. Below, the evidence and discussion among the committee members are summarised, and the final recommendations presented in italics.

RESULTS
Predisposing factors
Intrinsic and extrinsic risk factors may increase the chance of acute lateral ankle ligament injury or in short lateral ankle injury (LAI). In order to unravel the

Consensus statement

GMK and MvdB contributed equally to the manuscript.
importance of extrinsic risk factors for athletes, a specific search was performed for risk factors relating to the type of surface on which to play and the player position during the game.

**Intrinsic risk factors**

Four risk factors are important: strength, proprioception, range of motion and balance of players older than 15 years with a primary or recurrent lateral ankle ligament injury. The definition of LAI, ADL (activities of daily living) in the literature varied widely. There are indications that limited dorsal flexion and reduced proprioception lead to an increased risk of sustaining an LAI (Level 3). It is plausible that an ankle distortion in the past and reduced balance predispose for LAI, ADL.

**Extrinsic risk factors**

Among a group of 2 016 000 players of all kind of sports, 14 098 patients with LAI were selected of whom the medical files were available. The highest incidence of ankle injuries was reported due to playing soccer, basketball and field sports. The incidence is dependent on the type of sport, the total number of players and whether a competition is involved (Level 2). Among soccer players, playing on artificial grass seems to slightly increase the incidence (Level 2) and defenders and official grass seems to slightly increase the incidence (Level 2).

**Prognostic factors**

Research of high quality concerning the relationship between prognostic factors and LAI is lacking. The natural course is good; most patients with LAI show complete recovery over time. Pain decreases rapidly in the first 2 weeks after an ankle distortion (Level 1). After 1 year, 5% to 33% of the patients with LAI still have pain and have complaints of instability (Level 1). Sports performed at high level is possibly an unfavourable prognostic factor for the development of residual complaints (Level 3). Increased ligament laxity after an ankle distortion might also be an unfavourable prognostic factor for the development of chronic instability (Level 3).

Based on current research data, no recommendations concerning neither prognostic factors nor natural course of LAI can be made for daily practice.

**Ottawa ankle rules**

In LAI, ADL, the existence of a fracture is the main red flag. The ability to walk again within 48 h after trauma is an auspicious sign and indicates a good prognosis. The Ottawa Ankle Rules have been developed to rule out fractures after acute ankle injuries. Most patients who visit the emergency room are examined using radiographs to rule out fractures despite the fact that the prevalence of ankle fractures is less than 15%. The Ottawa Ankle Rules consists of a questionnaire and research protocol for examination of ankle and foot. X-ray diagnostics is only indicated in case of pain in the malleoli or middle foot, combined with one of the following findings: palpation pain on the dorsal side of one or both of the malleoli, palpation pain at the bases of the metatarsal bone, palpation pain of the navicular bone and finally if the patient is unable to walk at least four steps.

**Diagnoses**

If a haematoma is present accompanied by local pressure pain at palpation or a positive anterior drawer test is present or both, it is most likely that a (partial) lateral ankle ligament rupture exists. Delayed physical diagnostic examination (4 to 5 days) gives a better diagnostic result than research within 48 h. The sensitivity of delayed physical examination is 96% and the specificity 84% (Level 2). Knowledge about the
use of ultrasound and MRI examination and their diagnostic performance is hampered by lack of research (Level 4). Arthrography within 48 h after an inversion trauma is highly sensitive but not recommended (Level 2).36–39 For a solid diagnosis of an ankle ligament rupture, patients must be re-examined 4 to 5 days after the trauma.

If a haematoma develops and patients experience local pressure pain at palpation or a positive anterior drawer test is present or both, it is very likely that a ligament rupture exists.

**Treatment**

**The use of ice and compression in the inflammatory phase after acute ankle injuries**

In the event of an acute ankle injury, the effect of ice (cryotherapy) is unclear.40 Ice combined with exercise therapy has a positive effect on the swelling in comparison with heat application.41 The effectiveness of compression shows conflicting results (Level 2).42–44 Intermittent application of ice has a significant effect on short-term pain reduction (difference ± 1 cm in a visual analogue scale) in comparison with standard application of ice. There are no indications that the use of ice only is effective to reduce swelling, increase function and reduce pain at rest in the event of an acute ankle injury (Level 2).40–45 The use of ice and compression, in combination with rest and elevation, is an important aspect of treatment in the acute phase of LAI.

**Immobilisation after acute ankle injuries**

Research from a systematic review (21 randomised controlled trials (RCTs), N=2184) showed that a longer period of immobilisation in a lower leg cast (minimum of 4 weeks) is less effective compared with different functional treatments (Level 2) (see table 3).46 However, due to great variation in methodological quality, the conclusions from this review should be interpreted with some caution (Level 2).46 Recent evidence from 1 RCT (N=584) states that a short period of plaster immobilisation (10 days) or rigid support for reduction of pain and swelling can still be considered of help in the treatment of LAI.47

A short period of plaster immobilisation or similar rigid support facilitating a rapid decrease of pain and swelling can be helpful in the acute phase of the treatment of LAI.

Functional treatment for 4 to 6 weeks is preferable to immobilisation in a cast.

**Optimal functional treatment after acute ankle injuries**

A systematic review (9 RCTs, N=892) investigated the effect of different functional treatments for acute ankle injuries such as exercise therapy and immobilisation by means of tape or brace (Level 2) (see table 4).48 Elastic bandages gave fewer complications than tape, but was associated with a delayed return to work and sports. Instability was reported more frequently compared with a semirigid ankle brace. A lace-up brace or a semirigid brace seems preferable to the use of an elastic bandage (Level 2).48 However, in this review, insufficient data were present to draw definite conclusions from literature.

A lace-up brace or a semirigid brace is preferable and recommended. Based on consensus in the committee in (professional) sports also the use of tape can be considered.

**Exercise therapy after acute inversion injury**

Besides three recent RCTs,49–51 four systematic reviews of sufficient quality were found on this subject.52–55 Exercise therapy seems to prevent a recurrence in patients with LAI (2 RCTs, n=130) (RR 0.37; 95% CI 0.18 to 0.74) on the long term (8 to 12 months) (Level 2).54 Exercise therapy seems to have no (significant) effect on balance on the medium term (6 to 9 months) (2 RCTs, n=78) (SMD 0.28, 95% CI −0.15 to 0.91) (Level 2).54 Exercise therapy should be used in the treatment of LAI. Exercise therapy can also be applied at home.

**Manual mobilisation after acute ankle injuries**

Three systematic reviews were identified,52–54 the most recent review included all trials from the other two reviews.54 There are limited positive (very) short-term effects (dorsiflexion, ROM, proprioception) in favour of manual mobilisation of the ankle (6 RCTs, N=224) (Level 2).53–54 However, the clinical relevance of these findings is limited since the effects had disappeared 2 weeks after injury. Manual mobilisation of the ankle has limited added value and is not recommended.

**Other therapies after acute ankle injuries**

In literature, no effect was found of ultrasound, laser therapy55 and electrotherapy in the treatment of acute ankle injuries (Level 1). Short-wave therapy also seems ineffective (Level 2).50–64 Ultrasound, laser and electrotherapy have no added value and are not recommended.
Communication between healthcare professionals

In order to be able to effectively refine communication between healthcare professionals during referral of patients with LAI, the essential information has been inventoried by consensus of the guideline committee. A distinction was made between the diagnostic phase, the treatment phase and the guidance phase. The available information is presented in Table 5. The table is structured to ensure that healthcare professionals are informed of the essential diagnostic, treatment, and guidance aspects required for effective communication.

ADL, activities of daily living; LAI, lateral ankle injury.

Surgical therapy after acute lateral ankle ligament injury

A systematic review concluded that there was some limited evidence for longer recovery times, and higher incidences of ankle stiffness, impaired ankle mobility and complications after surgical treatment (20 RCTs, N=2562) (Level 2). However, final conclusion from this review was that there are insufficient high-quality RCTs available to give a final judgement on the effectiveness of surgery compared with conservative treatment in LAI (20 RCTs, N=2562) (Level 2). Functional treatment is preferred over surgical therapy.

Based on consensus in the committee, it is recommended that in (top-professional) sports surgical treatment can be considered on an individual basis.

DISCUSSION

A clinical guideline for acute lateral ankle ligament injury was developed under the auspices of the Royal Dutch Society for Physical Therapy by a group including content experts for all specialties involved, methodologists experienced in developing guidelines, health professionals involved in the healthcare process and patients. The idea behind guidelines is to provide a considered, unbiased, evidence-based, accessible, transparent and easy-to-use summary of the implications of current health knowledge for practice, which, if used, should improve the quality of care.

Guideline development is essential in improving ‘evidence-based practice’, but development is a complex process. Even good guidelines have tended to lie on shelves gathering dust because of the difficulty of distinguishing them from bad ones. At the start of this project, a limited set of relevant questions from daily clinical practice was selected to be answered by the guideline. Consequently, a possible weakness of the guideline is identified in the fact that there are still some issues open for debate. Another possible flaw is that even though the recommendations in this guideline are based on best evidence from literature, ultimately converting the evidence into recommendations was a consensus process among the committee members, leaving room for bias. However, having all relevant health professionals involved in the guideline committee has probably limited this bias.

A definite strength of the current guideline is that essential referral data are now available.
What is already known?

- The incidence and trauma mechanism of lateral ankle injury (LAI) are known.
- A variety of therapeutic interventions is available for restoring stability and diminishing pain and swelling in patients with LAI.
- There is still no uniform treatment of LAI despite the large number of clinical trials.

What this study adds

- A systematic, evidence-based guideline of the prevention, predictors, diagnosis, operative and conservative treatment and prognosis of lateral ankle injury (LAI) was lacking.
- This guideline incorporates a perspective from several healthcare professionals and patients with the clinical evidence to formulate a guideline concerning LAI.

available for refinement of communication between healthcare professionals, in the Netherlands and all over the world.

Future research is warranted to investigate a number of alternative prophylactic interventions, their cost-effectiveness and general applicability. Additionally, future research requires the design of high-quality randomised controlled trials of the best available conservative treatment for well-defined injuries, with special focus on the benefit of a short period of immobilisation in the treatment of LAI.
