It is time to bust the myth of physical inactivity and obesity: you cannot outrun a bad diet

A Malhotra,1 T Noakes,2 S Phinney3

A recent report from the UK’s Academy of Medical Royal Colleges described ‘the miracle cure’ of performing 30 min of moderate exercise, five times a week, as more powerful than many drugs administered for chronic disease prevention and management.1 Regular physical activity reduces the risk of developing cardiovascular disease, type 2 diabetes, dementia and some cancers by at least 30%. However, physical activity does not promote weight loss.

In the past 30 years, as obesity has rocketed, there has been little change in physical activity levels in the Western population.2 This places the blame for our expanding waist lines directly on the type and amount of calories consumed. However, the obesity epidemic only represents the tip of a much larger iceberg of the adverse health consequences of poor diet. According to The Lancet global burden of disease reports, poor diet now generates more disease than physical inactivity, alcohol and smoking combined. Up to 40% of those with a normal body mass index will harbour metabolic abnormalities typically associated with obesity, which include hypertension, dyslipidaemia, non-alcoholic fatty liver disease and cardiovascular disease.3 However, this is little appreciated by scientists, doctors, media writers and policymakers, despite the extensive scientific literature on the vulnerability of all ages and all sizes to lifestyle-related diseases.

Instead, members of the public are drowned by an unhelpful message about maintaining a ‘healthy weight’ through calorie counting, and many still wrongly believe that obesity is entirely due to lack of exercise. This false perception is rooted in the Food Industry’s Public Relations machinery, which uses tactics chillingly similar to those of big tobacco. The tobacco industry successfully stalled government intervention for 50 years starting from when the first links between smoking and lung cancer were published. This sabotage was achieved using a ‘corporate playbook’ of denial, doubt and confusing the public.4 Coca Cola, who spent $3.3 billion on advertising in 2013, pushes a message that ‘all calories count’; they associate their products with sport, suggesting it is ok to consume their drinks as long as you exercise. However science tells us this is misleading and wrong. It is where the calories come from that is crucial. Sugar calories promote fat storage and hunger. Fat calories induce fullness or ‘satiation’.

A large econometric analysis of worldwide sugar availability, revealed that for every excess 150 calories of sugar, there was an 11-fold increase in the prevalence of type 2 diabetes, in comparison to an identical 150 calories obtained from fat or protein. And this was independent of the person’s weight and physical activity level; this study fulfills the Bradford Hill Criteria for causation.3 A recently published critical review in nutrition concluded that dietary carbohydrate restriction is the single most effective intervention for reducing all the features of the metabolic syndrome and should be the first approach in diabetes management, with benefits occurring even without weight loss.6

AND WHAT ABOUT CARBOHYDRATE LOADING FOR EXERCISE?
The twin rationales for carbohydrate loading are that the body has a limited capacity to store carbohydrates and these are essential for more intense exercise. However, recent studies suggest otherwise. The work of Volek and colleagues7 establishes that chronic adaptation to a high-fat low-carbohydrate diet induces very high rates of fat oxidation during exercise (up to 1.5 g/min)—sufficient for most exercisers in most forms of exercise—without the need for added carbohydrate. Thus fat, including ketone bodies, appears to be the ideal fuel for most exercise—it is abundant, does not need replacement or supplementation during exercise, and can fuel the forms of exercise in which most participate.7 If a high-carbohydrate diet was merely unnecessary

for exercise it would be of little threat to public health, however, there are growing concerns that insulin-resistant athletes may be at risk of developing type 2 diabetes if they continue to eat very high-carbohydrate diets for decades since such diets worsen insulin resistance.

**THE ‘HEALTH HALO’ LEGITIMISATION OF NUTRITIONALLY DEFICIENT PRODUCTS MUST END**

The public health messaging around diet and exercise, and their relationship to the epidemics of type 2 diabetes and obesity, has been corrupted by vested interests. Celebrity endorsements of sugary drinks, and the association of junk food and sport, must end. The ‘health halo’ legitimisation of nutritionally deficient products is misleading and unscientific. This manipulative marketing sabotages effective government interventions such as the introduction of sugary drink taxes or the banning of junk food advertising. Such marketing increases commercial profit at the cost of population health. The Centres of Disease Control health impact pyramid is clear. Changing the food environment—so that individuals’ choices about what to eat default to healthy options—will have a far greater impact on population health than counselling or education. Healthy choice must become the easy choice. Health clubs and gyms therefore also need to set an example by removing the sale of sugary drinks and junk food from their premises. It is time to wind back the harms caused by the junk food industry’s public relations machinery. Let us bust the myth of physical inactivity and obesity. You cannot outrun a bad diet.

Sugar and carbs, not physical inactivity, behind surge in obesity, say experts

Time to bust myth that anyone—including athletes—can outrun a bad diet

Excess sugar and carbs, not physical inactivity, are behind the surge in obesity, say experts in an editorial in the *British Journal of Sports Medicine* published online today.

It’s time to bust the myth that anyone—and that includes athletes—can outrun a bad diet, they say.

Regular exercise is key to staving off serious disease, such as diabetes, heart disease, and dementia, write the authors, but our calorie laden diets now generate more ill health than physical inactivity, alcohol, and smoking combined.

The evidence now suggests that up to 40% of those within a normal weight (BMI) range will none the less harbour harmful metabolic abnormalities typically associated with obesity.

But few people realise this, and many wrongly believe that obesity is entirely due to lack of exercise, a perception that is firmly rooted in corporate marketing, say the authors.

They describe the public relations tactics of the food industry as “chillingly similar to those of Big Tobacco,” which deployed denial, doubt, confusion and “bent scientists” to convince the public that smoking was not linked to lung cancer.

“Celebrity endorsements of sugary drinks and the association of junk food and sport must end,” they declare, adding that health clubs and gyms need to set an example by removing the sale of these products from their premises. “The ‘health halo’ legitimisation of nutritionally deficient products is misleading and unscientific,” they write.

Public health messaging has unhelpfully focused on maintaining a ‘healthy weight’ through calorie counting, but it’s the source of the calories that matters, they point out. “Sugar calories promote fat storage and hunger. Fat calories induce fullness or satiation,” they write.

The prevalence of diabetes increases 11-fold for every 150 additional sugar calories consumed daily, compared with the equivalent amount of calories consumed as fat, they say.

And the evidence now suggests that carbs are no better, they add. Recent research indicates that cutting down on dietary carbohydrate is the single most effective approach for reducing all of the features of the metabolic syndrome and should be the primary strategy for treating diabetes, with benefits occurring even in the absence of weight loss.

Furthermore, other research suggests that rather than carbohydrate loading ahead of intense exercise, athletes would be better off adopting a high fat low carb diet, particularly those who are already insulin resistant.

The food environment needs to be changed so that people automatically make healthy choices, suggest the authors. This “will have far greater impact on population health than counselling or education. Healthy choice must become the easy choice,” they say.

“It’s time to wind back the harms caused by the junk food industry’s public relations machinery. Let’s bust the myth of physical inactivity and obesity. You can’t outrun a bad diet,” they conclude.
