PRE-SEASON HIP/GROIN STRENGTH AND RATINGS OF HEALTH ARE ASSOCIATED WITH PROSPECTIVE INJURY IN PROFESSIONAL FOOTBALLERS

Matthew Bourne*, Morgan Williams, Ryan Timmins, Tania Pizzari. School of Allied Health Sciences, Griffith University, Australia; 2School of Sport and Exercise Sciences, University of Jyväskylä, Finland; 3School of Behavioural and Health Sciences, Australian Catholic University, Australia; 4La Trobe Sport & Exercise Medicine Research Centre, La Trobe University, Australia

**Background** Hip and groin injuries are a significant cause of time lost from training and competition in elite football. **Purpose** To explore the association between hip/groin injury in professional footballers and pre-season assessment of 1) hip adductor and abductor strength, and 2) the Copenhagen Hip and Groin Outcome Score (HAGOS).  

**Study Design** Prospective cohort. 

**Methods** In total, n=204 elite male footballers from ten professional clubs underwent assessments of hip adductor and abductor strength and completed the HAGOS in pre-season. In-season hip/groin injuries were assessed and reported by team medical staff. Data reduction was conducted using principal component analysis. The subsequent factor component for HAGOS, and three factor components for strength and imbalance measures, were entered with age into a multivariate logistic regression model to determine their association with prospectively occurring hip/groin injury. 

**Results** Twenty-four players suffered at least one hip/groin injury throughout the 2017–18 competitive season. The principal component for between-limb abduction imbalance (peak strength in the preferred [kicking] limb – non-preferred limb) (OR=0.61, 95% CI 0.40 to 0.92), and the principal component for HAGOS (OR=0.80, 95% CI 0.64 to 0.99) were independently associated with a reduced risk of future hip/groin injury. Receiver operator curve analysis of the whole model revealed an area under the curve of 0.76. 

**Conclusion** These data demonstrate that a lower likelihood of prospective hip/groin injury during the season was associated with a hip abduction imbalance that favoured the preferred kicking limb and higher HAGOS obtained at pre-season.

FRONTAL PLANE FEMORAL ADDUCTION DURING SINGLE-LEG LANDING AND LOW BACK PAIN IN YOUNG ATHLETES: A PROSPECTIVE PROFITS COHORT STUDY

**Tampere Research Center of Sports Medicine, UKK Institute, Finland; 2School of Sport and Health Sciences, University of Jyväskylä, Finland; 3Sport Injury Prevention Research Centre, Faculty of Kinesiology, University of Calgary, Canada; 4Alberta Children’s Hospital Research Institute, University of Calgary, Canada; 5McCauley Institute for Bone and Joint Health, University of Calgary, Canada; 6Faculty of Information Technology, University of Jyväskylä, Finland; 7Oslo Sports Trauma Research Center, Department of Sports Sciences, Norwegian School of Sport Sciences, Norway

**Introduction** Prospective studies investigating risk factors for low back pain (LBP) in young athletes are limited. The aim of this prospective cohort study was to investigate the association between LBP and selected biomechanical factors and postural stability during dynamic movement tasks in young athletes.

**Materials and methods** 396 young floorball and basketball players (mean age 15.8±1.9) were included and followed prospectively for 1–3 years (2011–2014). In the beginning of every study year the players were tested. The physical tests included single-leg squat (SLS), single-leg vertical drop jump (SLVDJ), vertical drop jump (VDJ) and Star Reach Excursion Balance Test (SEBT). Individual exposure time and LBP resulting in time-loss were recorded prospectively. Cox’s proportional hazard models with mixed effects and time-varying risk factors were used. 

**Results** In SLVDJ landing with non-dominant leg, the risk for general LBP and non-traumatic LBP in specific, was significantly higher with increased femoral adduction (HR 1.10, 95% CI 1.02–1.19 and HR 1.12, 95% CI 1.03–1.22, respectively) and significantly lower with increased femur-pelvic angle (FPA; angle-between pelvis and femur) (HR 0.93, 95% CI 0.88–0.99 and HR 0.92, 95% CI 0.86–0.99, respectively). However, the ROC analysis revealed poor combined sensitivity and specificity for femoral adduction and for FPA. 

**Conclusions** Increased femoral adduction and decreased FPA during SLVDJ landing are associated with risk of LBP in young team ball players. However, the identified risk factors do not discriminate players with or without future LBP well enough and therefore further studies on effect of neuromuscular training on lumbo-pelvic control and LBP incidence are warranted.

IMPROVED DAILY MOVEMENT PATTERNS IN AN ACCELEROMETER-ASSESSED 8-WEEKS EXERCISE PROJECT IN OLDER ADULTS

Marie Godhe*, Orjan Ekbloom, Maria Ekbloom, Majan Pontén, MD Eva Andersson. 1The Swedish School of Sport and Health Sciences, Sweden; 2The Department of Neuroscience, Karolinska Institute, Sweden

**Background** Many beneficial health outcomes for elderly are associated with sedentary (SED) and physical activity behavior (PA). However, research is scarce regarding how elderly-interventions can improve various SED- and PA-behavior. 

**Purpose** The aim with this study was to determine if eight-weeks of regular supervised exercise would have any effect on movement-patterns in elderly. For comparison, a control group, not receiving supervised exercise, performed similar pre- and end-tests intervals. Reliability of elderly accelerometer measures, in two separate pre-tests was also investigated. 

**Methods** Seventy-eight elderly exercised (65–91 years) and 43 participated in a control group (65–88 years). The exercise group had combined aerobic and strength-training, twice/w à 1 hour. Accelerometer assessments for the exercise group were performed three times; Pre-1 and Pre-2 and one test in the last week of the 8-week-exercise-period. The controls made one pre-test and one end-test at corresponding spring time intervals, without receiving any supervised physical activity. 

**Results** The exercise-group significantly improved from Pre-1 to End-test moderate-to-vigorous-PA-intensity (MVPA +41 min/week=+0.8% of-total-daily-wear-time), light-intensity (LPA +228 min/w=+3.9%), total-SED-time (–254 min/w=–4.7%) and SED-bouts-à–10 min (–320 min/w=–5.7%). The controls showed no significant improvements.
from pre-1-to-End-tests, except for LPA (+2.3%) and total-SED-time (and −2.7%). Total-daily-counts in the End-test increased for controls (+6.7%) but significantly more for the exercise group (+17.3%). Between the exercise groups’ two pre-tests, no significant difference was observed, except for total-PA (+4.6%) and SED-total (−2.4%).

**Conclusion** Elderly participating in supervised exercise increase PA- and decrease SED-time, which is of importance because it is linked with improved health for elderly, longevity and potent socioeconomic gains.

**PLATELET RICH PLASMA FOR ACUTE ACHILLES TENDON RUPTURE: A DOUBLE-BLEND, MULTICENTRE, RANDOMISED, PLACEBO-CONTROLLED TRIAL**

1David Keene*, 1Joseph Alsousou, 1Paul Harrison, 1Philippa Hulley, 1Susan Wagland, 5Scott Parsons, 1Jacqueline Thompson, 1Heather O’Connor, 1Michael Schüssel, 1Susan Dutton, 1Sarah Lamb, 1Keith Willett. 6University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, UK; 2University of Liverpool, Institute of Translational Medicine, UK; 3University of Liverpool, Institute of Inflammation and Ageing, UK

**Introduction** Platelet Rich Plasma (PRP), an autologous supra-physiological concentration of platelets from whole blood, has demonstrated positive cellular and physiological effects on healing in the laboratory. However, evidence from robust clinical trials is lacking. We aimed to determine the clinical efficacy of PRP for treating acute Achilles tendon rupture.

**Materials and methods** 230 adults starting non-surgical management within 12 days of rupture were randomised to PRP injection or dry needle insertion, under local anaesthetic. Participants were blinded and received standardised rehabilitation. Blinded outcome assessments were at 4, 7, 13, and 24 weeks. Primary outcome: muscle-tendon function assessed by work management within 12 days of rupture were randomised to PRP injection or dry needle insertion, under local anaesthetic. Participants were blinded and received standardised rehabilitation. Blinded outcome assessments were at 4, 7, 13, and 24 weeks. Primary outcome: muscle-tendon function assessed by work.

**Results** Of 230 participants, 114 were allocated to PRP injection (103 received PRP), 116 were allocated to receive placebo. At 24 weeks, 201/230 (87%) completed the HRET (103 received PRP), 116 were allocated to and received placebo. At 24 weeks, 201/230 (87%) completed the HRET and 214/230 (93%) completed patient-reported outcomes. Participant characteristics between the groups were similar. There was no difference between groups at 24 weeks in LSI (mean difference = −0.373; 95% CI −1.121, 2.471; p = 0.195). There were no differences in the secondary outcomes and adverse event rates.

**Conclusion** This study design and standardised PRP preparation secure robust clinical trial evidence for PRP in managing Achilles tendon rupture, and suggest that PRP offers no patient benefit. Use of PRP in soft tissue injuries must be questionable unless supported by equally robust evidence indicating positive outcomes.

**THE EFFECT OF CHANGE OF DIRECTION ANGLE ON KNEE MECHANICS – IMPLICATIONS FOR ACL INJURY**

Ayman Alhammad*, Lee Herrington, Paul Jones, Ritchard K Jones. School of Health Sciences, University of Salford, UK

**Introduction** Change of direction (COD) manoeuvres are important for many field sports, however they are unfortunately associated with non-contact ACL injuries. Although players frequently COD at >90° angles, limited knowledge is available on knee joint kinematics and kinetics during COD at 90° and 135° and whether limb preference impacts knee mechanics during COD at these angles, which formed the aims of this study.

**Methods** Healthy male recreational soccer players were recruited to take part in the study. 3D kinematics and kinetics were collected during COD manoeuvres at 90° and 135°. Running speed was controlled at 4±0.4 m/s and 3.5±0.3 m/s, respectively. To determine differences on variables associated with ACL risk; knee abduction angle and moment, across cutting angles and preferred legs, a paired sample t-test was conducted using a Holm method correction, α=0.05/ (8 comparisons − rank +1).

**Results** 36 individuals took part in the study (24.25±6.21 years, 1.72±0.06 m and 66.41±10.83 kg). COD at 135° showed greater knee abduction angles and moments than at 90° but with similar peak VGRF. There were no differences between preferred and non-preferred legs, apart from the increased knee flexion angle during COD manoeuvres at 90° in the non-preferred leg.

**Conclusion** In male recreational soccer players, sharper cutting angles place the knee at more risk for ACL injuries with little asymmetry between preferred and non-preferred limbs. Sharper angles of examination should be utilized in the evaluation of individuals.

**CHANGE IN PATIENT-REPORTED OUTCOMES FOLLOWING MENISCAL REPAIR COMPARED WITH RESECTION IN YOUNG ADULTS: SECONDARY ANALYSES FROM A PROSPECTIVE COHORT STUDY**

1Kenneth Pihl*, 2,3Martin Englund, 4,5Robin Christensen, 4Stefan Lohmander, 6Uffe Jørgensen, 7No Nissen, 8Jacob V Fristed, 1Jonas B Thorlund. 1Department of Sports Science and Clinical Biomechanics, University of Southern Denmark, Denmark; 2Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Orthopedics, Clinical Epidemiology Unit, Sweden; 3Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, USA; 4Musculoskeletal Statistics Unit, The Parker Institute, Copenhagen University Hospital, Denmark; 5Department of Rheumatology, Odense University Hospital, Denmark; 6Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Orthopedics, Sweden; 7Department of Orthopedics and Traumatology, Odense University Hospital, Denmark; 8Department of Orthopedics, Lillebaelt Hospital, Denmark

**Introduction** Young adults, meniscal repair may be an alternative to resection. We compared change in patient-reported outcomes from before to 52 weeks after arthroscopic surgery in younger patients having either meniscal repair or resection.

**Materials and methods** Patients aged 40 or younger from the Knee Arthroscopy Cohort Southern Denmark (KACS) study undergoing arthroscopic meniscal surgery. Patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) online at pre-surgery, 12 and 52 weeks follow-up. Between-group differences in change in a composite of 4 of 5 KOOS subscales (KOOS5) from baseline to 52 weeks were analyzed using repeated measures mixed linear models.
