12 EFFICACY OF EARLY CONTROLLED MOTION OF THE ANKLE IN NON-OPERATIVE TREATMENT OF ACUTE ACHILLES TENDON RUPTURE. AN ASSESSOR-BLINDED RCT

Kristoffer Weisskirchner Barfod*, 1Maria Swennergren Hansen, 1Per Holmich, 2Morten Tange Kristensen, 3Anders Troelsen, 4Sports Orthopedic Research Center – Copenhagen (SORC-C), Arthroscopic Center, Department of Orthopedic Surgery, Copenhagen University Hospital, Amager-Hvidovre, Denmark; 2Physical Medicine and Rehabilitation Research – Copenhagen (PMR-C), Department of Physiotherapy and Occupational Therapy, Copenhagen University Hospital Hvidovre, Denmark; 3Department of Orthopaedic Surgery, Clinical Orthopaedic Research Hvidovre, Copenhagen University Hospital Hvidovre, Denmark

Abstracts

Background Early controlled ankle motion (ECM) is widely used in the non-operative treatment of acute Achilles tendon rupture although its safety and efficacy has not been investigated properly in a randomized setup.

Purpose/aim of the study To investigate if ECM of the ankle was superior to immobilization (IM) in the treatment of acute Achilles tendon rupture.

Materials and methods The study was performed as an assessor blinded randomized controlled trial with patients allocated in a 1:1 ratio to one of two parallel groups. Patients aged 18 to 70 years were eligible for inclusion. The ECM group performed movements of the ankle 5 times a day from week 3 to 8 after rupture. The control group was immobilized (IM). The primary outcome was the Achilles tendon Total Rupture Score (ATRS) evaluated at 1 year post-injury. Secondary outcomes were: heel-rise-work test (HRW), Achilles tendon elongation and rate of re-rupture. Analysis was conducted as intention-to-treat with imputation of missing data.

Findings/results 189 patients were assessed for eligibility and 130 included from September 2014 to December 2016; 64 ECM and 58 IM. There was no statistically significant differences (p>0.3) between the ECM and IM groups at 1 year; Mean (SD) ATRS was 74 (18) and 75 (18), respectively, HRW was 60% (21) and 60% (21) of the uninjured limb, and elongation was 18 mm (13) and 16 mm (11), respectively. Correspondingly, there were 6 and 7 re-ruptures. Conclusions ECM revealed no benefit to IM in any of the investigated outcomes.

ACUTE ACHILLES TENDON RUPTURE – THE INFLUENCE OF GENDER, AGE AND COMORBIDITY ON TREATMENT OUTCOME

1Allan Cramer*, 1Nanna Cecile Jacobsen, 2Maria Swenngren Hansen, 3Håkon Sandholt, 1Per Hölmi, 1Kristoffer Barfod. 1Sports Orthopedic Research Center – Copenhagen (SORC-C), Arthroscopic Center, Department of Orthopedic Surgery, Copenhagen University Hospital, Amager-Hvidovre, Denmark; 2Physical Medicine and Rehabilitation Research – Copenhagen (PMR-C), Denmark; 3Clinical Orthopedic Research Hvidovre (CORH), Copenhagen University Hospital, Amager-Hvidovre, Denmark

Introduction Studies suggest that women have worse treatment outcome than men after acute Achilles tendon rupture (ATR). Few studies have assessed the influence of age and comorbidity on treatment outcome after ATR. The aim of the study was to investigate if gender, age and comorbidity affect patient reported outcome following ATR.

Materials and methods The study was performed as a registry study in the Danish Achilles tendon Database. The endpoints were the Achilles tendon rupture score (ATRS) at 4 months, 1 year and 2 years after injury. Variables of interest were gender, age, diabetes, hypertension, rheumatic disease, smoking and previous Achilles tendon disorder.

Results Data were collected from April 2012 to March 2018. 1524 patients participated at 4 months, 1277 at 1 year and 899 at 2 years. Women had statistically significantly lower ATRS at 4 months (mean difference, [confidence interval], p-value) (4.8, [1.78;7.78], p<0.01) and 1 year (9.9, [4.3;15.5], p<0.01), but not after 2 years. Patients with hypertension (7.6, [1.4;13.8], p=0.02) and non-operatively treated patients with rheumatic disease (14.8, [0.4;29.2], p=0.04) had lower ATRS at 1 year. Age showed a weak correlation to ATRS at 1 year (r=0.12; p<0.01).

Conclusion Women scored statistically significantly less than men in ATRS at 4 months and 1 year after ATR. The difference was half the clinically relevant difference at 4 months and peaked at 1 year where it equaled the clinically relevant difference. Hypertension and rheumatic disease led to statistically significantly decreased ATRS. Age did not have clinical relevant influence on ATRS.

RELATIONSHIPS BETWEEN A MULTIDIRECTIONAL REACTIVE AGILITY TEST, FUNCTIONAL PERFORMANCE AND PATIENT-REPORTED OUTCOME MEASURES 6 MONTHS AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

1Bart Dingener*, 2Jan Truijen, 2Johan Bellemans, 4,5,6Alli Gokeler. 3Rehabilitation Research Centre, Biomedical Research Institute, Faculty of Medicine and Life Sciences, UHasselt, Agoralaan A, Belgium; 2Department of Orthopedic Surgery, Ziekenhuis Oost-Limburg, Belgium; 4Faculty of Medicine and Life Sciences, UHasselt, Agoralaan A, Belgium; 5Luxembourg Institute of Research for Orthopedics, Medicine and Science in Sports, Luxembourg; 6Applied Neuroscience in Sports and Exercise, Department Exercise and Health, Faculty of Science, University of Paderborn, Germany; 7University of Groningen, University Medical Center Groningen, Center for Human Movement Sciences, The Netherlands

Introduction Return-to-sport testing after anterior cruciate ligament (ACL) reconstruction traditionally occurs during pre-planned activities. The aim of this study was to investigate the relationships between a novel multidirectional reactive agility test, functional performance and patient-reported outcome measures in athletes after ACL reconstruction.

Materials and methods Twenty-eight ACL-reconstructed athletes (24 males, 4 females; 24.6±4.4 years; 6 months postoperative), participated in the study. All athletes underwent an evaluation including a novel multidirectional reactive agility test (tested with Smartgoals, a light-based reactive training system to measure the time to complete a task), functional performance tests: 1) two hop tests (single-leg hop for distance, triple hop for distance), 2) the Y-balance test conducted with eyes closed and patient-reported outcome measures (ACL-Return to Sports after Injury (ACL-RSI) scale, Knee Self-Efficacy Scale (K-SES), International Knee Documentation Committee (IKDC) subjective knee form). Spearman correlation coefficients were calculated between the outcomes on the multidirectional reactive agility test, and the functional performance and patient-reported outcome measures.

Results The time to complete the multidirectional reactive agility test was significantly (p<0.05) negatively correlated with absolute hop test distances (r=−0.52 to −0.53), hop tests limb symmetry indices (r=−0.41 to −0.49), postero medial (r=−0.64) and posterolateral (r=−0.61) reach distances on the Y-balance test, and K-SES future (r=−0.39), ACL-RSI (r=−0.39) and IKDC scores (r=−0.44).

Conclusion Faster reactive agility was significantly correlated with better functional performance and patient-reported outcome measures. These results suggest to consider implementing multidirectional reactive agility testing within the continuum of the return-to-sport decision-making process in athletes after ACL reconstruction.

SUBCLASSIFICATION OF RECREATIONAL RUNNERS WITH A RUNNING-RELATED INJURY BASED ON RUNNING KINEMATICS MEASURED WITH TWO-DIMENSIONAL VIDEO ANALYSIS

1Bart Dingener*, 2Filip Staes, 1Romy Vanelderen, 1Linde Ceyssens, 3,5Peter Malliaras, 4,5,6Christian Barton, 2Kevin Deschamps. 1Rehabilitation Research Centre, Biomedical Research Institute, Faculty of Medicine and Life Sciences, UHasselt, Agoralaan A, Belgium; 2KU Leuven Musculoskeletal Rehabilitation Research Group, Department of Rehabilitation Sciences, Faculty of Kinesiology and Rehabilitation Sciences, Belgium; 3Department of Physiotherapy, School of Primary and Allied Health Care, Faculty of Medicine, Nursing and Health Science, Monash University, Australia; 4La Trobe Sport and Exercise Medicine Research Centre, School of Allied Health, La Trobe University, Australia; 5Complete Sports Care, Australia; 6Department of Surgery, St Vincent’s Hospital, University of Melbourne, Australia; 7KU Leuven, Department of Rehabilitation Sciences, Faculty of Kinesiology and Rehabilitation Sciences, Campus Bruges, Belgium

Introduction The aim of this study was to explore whether homogeneous subgroups could be classified within the running kinematics of a group of recreational runners with a running-related injury (RRI).

Materials and methods Fifty-three recreational runners (15 males, 38 females) with an RRI ran on a treadmill at preferred speed. Digital videos were recorded in the frontal and sagittal plane with two iPads. Outcome measures included foot and tibia inclination at initial contact, and hip adduction and knee flexion during midstance. All angles were manually
