Conclusions Injury incidence in German elite hockey players were lower than in comparable studies. Localization was almost similar to findings in other studies. No/less other studies recording the wearing behavior of PPE. Injury mechanism and correlation with wearing behavior of PPE should be examined to develop further preventive measures.

Background There is a gap between evaluating injury prevention interventions and use in practice. Implementation research aims to transfer interventions beyond research.

Objective The aim of this study was to find out whether what implementation processes took place during effectiveness studies targeting injury prevention programs, what factors hindered or facilitated this process and what activities and support were provided to promote implementation during the trial.

Design We conducted a systematic review and sent out an online survey targeting authors of included studies.

Setting Papers investigating all levels of sports (amateur, general sporting population, recreational, university, youth, and professional) were included.

Patients (or Participants) Authors of studies included in the review reporting effectiveness evaluations of injury prevention programs were contacted. Papers eligible for the survey were depicted from the review from Vriend et al. (2017) (n = 81) and updated papers (n = 31), which resulted in 112 included papers, describing 105 injury prevention programs.

Interventions (or Assessment of Risk Factors) The survey took 15 minutes to complete and could be taken only once. Participants were contacted by email and received a reminder twice.

Main Outcome Measurements The survey asked what materials and activities for implementation processes took place during a trial. To ensure a greater impact, future studies should document their activities more detailed and formally.

Background Over the last 50 years kinesiotaping has become a very popular adjunct in the treatment of sports injuries. Its role in sports injury prevention however remains unclear.

Objectives To investigate whether kinesiotaping has a role in the prevention of sports injuries.

Methods An electronic search was conducted up to June 2019 using medical subheadings and free-text words. The subject-specific search included the terms ‘Kinesio tape’, ‘injury prevention’, ‘motor control’, and ‘proprioception’. The search included levels 1, 2 and 3 evidence-based articles.

Results Twenty-one articles were found. The majority of the articles did not support the use of Kinesio tape in the prevention of injury nor in the increase of joint positioning sense, proprioception or increased motor control.

Conclusions It remains questionable whether Kinesio tape should be used in order to prevent sport injury.
