Results 55 participants reported with a median time of 63 days (95%CI: 35–133) a severe health problem. Women had significantly (p=0.02) shorter median time to first health problem (35 days; 95%CI: 7–105) compared to men (98 days; 95%CI: 49–294) and nearly twice as high risk to sustain a severe health problem (HR: 1.88; 95%CI: 1.1–3.24). Age or impairment comparisons showed no significant differences. Injuries at the shoulder resulted in the highest burden with 6.5 time loss days per athlete per year followed by the hand (2.9) and trunk (2.6). Respiratory infections showed the highest burden with 5.2 time loss days per athlete per year followed by genitourinary illnesses (1.9) and infectious diseases (1.8).

Conclusion Sex but not age or impairment type showed significant differences on time to health problem and enhanced risks. Upper body injuries and respiratory infections generated high burden.

449 SPORTS INJURIES IN ADAPTED SPORTS: A SYSTEMATIC REVIEW WITH QUALITY ASSESSMENT

1Sietse Luijten, 2Leonie te Loo, 1Joske Nauta, 1Thomas Jansen, 3Jasmijn Holla, 4René Otten, 1Ingrid Vriend, 1Evert Verhagen. 1Department of public and occupational health, Amsterdam UMC, Amsterdam, Netherlands; 2Sport Studies, Inholland University of Applied Sciences, Haarlem, Netherlands; 3Faculty of behavioural and movement sciences, Vrije Universiteit, Amsterdam, Netherlands; 4Faculty of Health, Sports and Social Work, Inholland University of Applied Sciences, Haarlem, Netherlands; 5Amsterdam Rehabilitation Research Center, Reade, Amsterdam, Netherlands; 6Medical Library, Vrije Universiteit, Amsterdam, Netherlands; 7Amsterdam Public Health research institute, Amsterdam, Netherlands

Background Participation is sport associated with a risk of sports injuries and illnesses. For athletes with an impairment, sports related health issues pose further burden upon an already restricted lifestyle. This underlines the importance of injury prevention in adapted sports.

Objective To provide an overview of the current evidence regarding injuries and their prevention in adapted sports.

Design A systematic review with quality assessment.

Setting Peer-reviewed literature on sports injuries in adapted sports.

Participants Individuals with a physical impairment that affects motor function, and who are active in sports or physical activity.

Assessment of Risk Factors This study was conducted in accordance with the ‘Preferred Reporting Items for Systematic Reviews and Meta-Analyses’ (PRISMA) guidelines.

Main Outcome Measurements Literature and evidence was categorised by the sequence of prevention; i.e. (1) problem magnitude; (2) aetiology of injury; (3) development of preventive measures; and (4) evaluation of effectiveness.

Results 52 studies were included. A total of 5 studies reported on the first step of the sequence of prevention (problem magnitude) only. 28 studies reported information on both the first and second step, 15 studies on only the second step and only 4 studies on the third and fourth step of the sequence. Most studies included participants of an elite level (82.7%). There is a wide range of injury and illness incidence between various sports (2.2 - 90.9 per 1000 athlete days) and impairment categories (0.6 - 50.0 per 1000 athlete days).

Conclusions Current evidence regarding injuries in adapted sports is mostly limited to elite level athletes. The evidence regarding the development of preventive measures and their effectiveness is limited in this target group. More knowledge is needed of the aetiology and risk factors of various adapted sports, physical impairments and level of performance to develop future prevention strategies for this population.

450 INJURY RATES, TYPES AND MECHANISMS IN SLEDGE HOCKEY: IMPLICATIONS FOR GRASSROOTS THROUGH ELITE PARTICIPATION

1Alexandra J Sobry, 1Ash T Kolstad, 1Leticia Janzen, 1,2,3,4Amanda M Black, 1,2,3,5,6Carolyn A Emery. 1Sport Injury Prevention Research Centre, Faculty of Kinesiology, University of Calgary, Calgary, Canada; 2Alberta Children’s Hospital Research Institute, University of Calgary, Calgary, Canada; 3Hotchkiss Brain Institute, University of Calgary, Calgary, Canada; 4Community Health Sciences, Cumming School of Medicine, University of Calgary, Calgary, Canada; 5McCaig Institute for Bone and Joint Health, University of Calgary, Calgary, Canada; 6Medical Library, Vrije Universiteit, Amsterdam, Netherlands; 7McCaig Institute for Bone and Joint Health, University of Calgary, Calgary, Canada

Background Sledge hockey is a contact sport played on an artificial ice surface. Sledge hockey has become increasingly popular and is considered part of the Winter Olympic Games. There is limited research in sledge hockey regarding injury rates, types and mechanisms. This study was performed to provide a comprehensive overview of injury rates and types and mechanisms seen in sledge hockey. Recommendations for injury prevention are provided.

Methods The study is a prospective cohort study over three seasons, in British Olympic track and field athletes over three full training and competition seasons. A total of 6,548 athlete days were followed prospectively for three consecutive seasons was 79,205 athlete days (217 athlete years). Team medical personnel recorded all injuries and illnesses during this time, following current consensus-based methods.

Main outcome measures Exposure, incidence, severity, burden, mechanism- acute vs overuse

Methods A total of 111 athletes on the British national programme were followed prospectively for three consecutive seasons between 2015–2018. Team medical personnel recorded all injuries and illnesses during this time, following current consensus-based methods.

Results The average age of the athletes was 24 years for both males and females (24 years, SD: 4). Total exposure for the three seasons was 79,205 athlete days (217 athlete years). Overuse injuries (56.4%) were more frequent than acute injuries (43.6%). The thigh was the most common injury location (0.6 per athlete year), followed by the lower leg (0.4 per athlete year) and foot (0.3 per athlete year). Muscle and tendon were the most commonly injured tissues, while strains and tears were the most common pathology type. Respiratory illness was the most common illness type (0.3 per athlete year). Hamstring muscle strain was the most common diagnosis causing time loss, followed by Achilles tendinopathy and soleus strain.

Conclusion Our findings indicate that future injury prevention efforts within elite athletics need to focus specifically on hamstring strains, Achilles tendinopathy, and soleus strains. Improved knowledge of the aetiology and risk profile of these problems in elite athletes is needed.
Conclusions
Concussions and upper extremity injuries were not found to be injury risk factors. Age, sex, disability type, and level of play was body checking (42.1% of injuries caused by contact with another player). Age, sex, disability type, and level of play were not found to be injury risk factors.

Conclusions Concussions and upper extremity injuries were the most common sledge hockey injuries reported, with body checking being the most common mechanism. This research will inform the development of sledge hockey injury prevention strategies.

452 ABSTRACT WITHDRAWN

453 HIGH LEVEL OF ORAL DISEASE AND SELF-REPORTED PERFORMANCE IMPACTS IN MALAYSIAN ELITE ATHLETES

Background Oral health can affect performance, including athletes who always need to be in their best conditions during training and competitions. However, oral health awareness has never been a priority among Malaysian athletes.

Objective This study primarily aimed to assess the association between oral health status and self-reported impact on athletes’ sports performance, using the Oral Health Screening Toolkit for Athletes developed by University College London, UK.

Design/Setting/Participants This is a cross-sectional study using convenience sampling. Data were collected among elite athletes registered under the National Sport Council (NSC), Malaysia.
