ball pass before and after a high-speed 180° pivot turn on the force plates.

Following variables were analysed

Peak vertical ground reaction force (N/kg), peak trunk lateral flexion angle (degree), peak knee flexion angle (degree), peak knee valgus angle (degree), peak knee flexion moment (Nm/kg), peak knee abduction moment (Nm/kg), and peak knee internal and external rotation moments (Nm/kg). Mean of three trials was used. Injuries and exposure were registered for 12 months.

Main Outcome Measurements New acute non-contact knee injury.

Results The complete data was obtained from 109 female and 149 male basketball (n=130) and floorball (n=128) players. A total of 18 new non-contact knee injuries were registered (0.3 injuries/1000 h of exposure). Female players sustained 14 knee injuries and male players 4. A higher rate of knee injuries was observed in females compared with males (incidence rate ratio 6.2, 95% CI 2.1–21.7). Eight ACL injuries were registered (all in female players). Females displayed significantly larger peak knee valgus angles compared with male (mean for female and male, respectively: 13.9 and 2.0 degree). No significant associations between biomechanical variables and knee injury risk were found.

Conclusions Female players were at increased risk of knee and ACL injury compared with males. Female players performed the 180-degree pivot turn with significantly larger knee valgus compared with male. However, none of the investigated variables were associated with knee injury risk in youth basketball and floorball players.

Main Outcome Measurements Inter-team comparisons were calculated using the following formula: ‘Cumulative injury burden resulting from mandatory reportable injuries (24 days) per team-season/number of competitive matches per team-season’.

Results Every German professional handball player missed on average (cumulative) 28.7 days per season due to injuries. The total burden equaled 66,597 days of absence (HB: 31,247, HB2: 35,350). The mean injury burden per competitive match over the three observed seasons for all HB teams ranged from 12.5 to 14.2 days of absence with individual rates ranging from 4.3 to 28.8 (2014/2015), 2.1 to 27.5 (2015/2016) and 2.3 to 33.6 (2016/2017). For HB2 teams the mean burden ranged from 13.3 to 14.6 days of absence per competitive match, with individual rates ranging from 3.0 to 25.1 (2014/2015), 2.5 to 30.0 (2015/2016) and 0.9 to 35.7 (2016/2017).

Conclusions These wide ranges indicate that a reduction in the injury burden seems generally possible and that some teams and coaching staffs are more successful concerning their preventive (coach, medical and therapeutic specific) player support.
