Promotion of Para Athlete Well-being in South Africa (The Propel Studies), Part II: Identification of Sleep-associated Risk Factors

Wayne Derman, J Craig Brown, Marelise Badenhorst, Phoebe Runciman

Objective To evaluate sleep quality, sleepiness and chronotype of para athletes in South Africa.

Background Good sleeping habits are necessary for optimal practice and performance, as well as for athlete health. Although the sleep characteristics of elite athletes are well described, research is limited on the sleep profile of similar level para athletes.

Main Outcome Measurements Pittsburgh Sleep Quality Index (PSQI), the Epworth Sleepiness scale and Morningness-Eveningness Questionnaire (MEQ-SA).

Results Fifty-eight percent (58%) of athletes identified as morning types, while 38% identified as intermediate types. Forty-eight percent (48%) were classified as having ‘good’ sleep quality, and the ‘sleepiness’ group were associated with the ‘poor’ quality sleep group (p=0.04, V=0.19). Additionally, athletes with ‘poor’ sleep quality were associated with shorter sleep duration (p=0.001, V=0.63), lower sleep efficiency (p=0.001, V=0.45), greater daytime dysfunction (p<0.001, V=4.0) and greater sleep disturbances (p<0.001, V=34).

Conclusions The majority of athletes in this study presented with poor sleep quality. These findings demonstrate a need to identify, address and prevent possible mechanisms affecting poor sleep quality in this population.

Promotion of Para Athlete Well-being in South Africa (The Propel Studies), Part III: Factors Associated with Mental Health

Marelise Badenhorst, J Craig Brown, Phoebe Runciman, Wayne Derman

Objective To further understand and identify mechanisms affecting mental health in this population.

Background There is a paucity of research investigating the mental health profiles of para athletes globally, especially in South Africa.

Main Outcome Measurements Mental health was measured with the Trait component of the State/Trait Anxiety Inventory (STAI) and the Kessler Psychological Distress Scale (K-10).

Results The mean K-10 questionnaire score was 40.3 ±9.3; females) with a mean age 26.7 (±9.2). Interventions (or Assessment of Risk Factors) Between-group differences were analysed using the Mann-Whitney U test or one-way ANOVA. On completion of the questionnaires, all athletes were given information about mental health support services.

Conclusions The study found high rates of psychological distress among para athletes, which is an important first step towards the development of prevention strategies. There is a need to further understand and identify mechanisms affecting mental health in this population.
Background Para athletes may have specific mental health challenges that, together with the demands of high-level sports performance, could put them at risk for mental health disorders.

However, research in this population is limited.

Objective To investigate factors associated with mental health in South African para athletes.

Design Descriptive, cross-sectional survey.

Setting National to international level athletes competing in the 2019 National Championships.

Patients (or Participants) A total of 124 athletes (93 males; 31 females) with a mean age 26.7 (±9.2) were included in the study.

Interventions (or Assessment of Risk Factors) Demographic, medical history and sleep-related variables were included in bivariate analyses to assess their association with mental health. Between-group differences were analysed using the Mann-Whitney U or T-tests. Variables significantly associated in the bivariate analyses were included in multiple regression analyses for mental health.

Main Outcome Measurements Mental health was measured with the State/Trait Anxiety Inventory (STAI) and the Kessler Psychological Distress Scale (K-10 Questionnaire). Sleep quality, sleepiness and chronotype were measured with the Pittsburgh Sleep Quality Index (PSQI), the Epworth Sleepiness scale and Morningness-Eveningness Questionnaire (MEQ-SA).

Results The model explained 40% of the variance in mental health (F=12.04, p<0.001) in these athletes. Compared to athletes with ‘good’ sleep quality, K-10 and STAI scores were significantly higher (indicating poorer mental health) in athletes with ‘poor’ sleep quality (U =2.6, p<0.001; t(116.8)=-4.30, p<0.001). ‘Poor’ sleep quality (B:0.8; 95% CI 0.4 to 1.3), moderate to severe daytime sleepiness (B:4.2; 95% CI 1.1 to 7.3) intermediate (B:3.5 95% CI 0.4 to 6.6) and evening chronotypes (B:12.0 95% CI 5.0 to 19.1), the presence of allergies (B:3.9 95% CI 0.1 to 7.6) and male gender (B:3.3 95% CI 0.1 to 6.5) were most strongly associated with high STAI scores.

Conclusions This study has identified novel factors associated with poor mental health in elite para athletes. As some of these factors are modifiable, further research towards prevention strategies is warranted.

Objective To examine associations between suicidal ideation and sexual and physical abuse among active and recently retired elite Athletics (track and field) athletes.

Design Cross-sectional study.

Setting Swedish elite Athletics.

Participants Athletes (n=402) who had been selected for a Swedish Athletics team for international competitions between 2011 and 2017.

Assessment of Risk Factors Lifetime experience of sexual and physical abuse, athlete personal and sociodemographic characteristics, Athletics participation, sense of coherence (SOC-13), and coping strategies (Brief Cope).

Main Outcome Measurements Suicidal ideation and 1-year period prevalence of non-sports injury.

Results 192 athletes (47.8%) returned complete data sets. The prevalence of suicidal ideation was 15.6% (males 17.4%; females 14.2%) and the non-sports injury prevalence was 8.0% (males 11.6%; females 5.7%). Suicidal ideation was among females (Nagelkerke $R^2=0.33$) associated with sexual abuse victimization (Odds ratio (OR) 5.94, 95% Confidence interval (CI) 1.42–24.90; P=0.015) and lower sense of coherence (OR 0.90, CI 0.85–0.96; P=0.001). Among males ($R^2=0.25$), suicidal ideation was only associated with use of behavioural disengagement for coping (OR 1.51, CI 1.18–1.93; P=0.001). Non-sports injury prevalence was among females ($R^2=0.23$) associated with sexual abuse victimization (OR 8.61, CI 0.02–90; P=0.039) and participation in an endurance event (OR 7.37, CI 1.11–48.90; P=0.039), while among males ($R^2=0.11$) only having immigrant parents (OR, 5.67, CI 1.31–24.45; P=0.020) was associated with having sustained an injury outside sports.

Conclusions Given that about one out of six athletics athletes had experienced suicidal ideation, the present results warrant and can be used in suicide prevention among elite athletes.

Background Sports-related injuries and illnesses in Paralympic sport is a growing concern, but knowledge about the aetiology and risk factors is limited.

Objective To describe the annual incidence of injuries and illnesses among Paralympic athletes and to assess risk factors.

Design Prospective cohort study.

Setting Paralympic athletes.

Patients (or Participants) 107 Swedish Paralympic elite athletes with vision, physical and intellectual impairments, active in 19 para sports.

Interventions (or Assessment of Risk Factors) The athletes were asked to weekly report over 52 weeks the annual incidence of injuries, illnesses and quality of health in an adapted eHealth application.

Main Outcome Measurements Time to event, incidence rate (IR) and incidence proportion (IP) and risk factors.
