Setting High schools in Alberta, Canada.
Participants Female students who reported playing one of the top ten team sports for participation (i.e., baseball, basketball, lacrosse, soccer, volleyball, football, rugby, ringette, field hockey, ice hockey).

Assessment of Risk Factors
A 45-minute survey included questions regarding demographic information, sport participation, and one-year injury and concussion history.

Main Outcome Measurements Self-reported injuries sustained in the past year.

Results 51.7% (1048/2029) of high school students completing the survey were female and 481/1048 (45.9%) reported playing at least one team sport. Of these, 51.4% reported at least one sport-related injury and 8.9% at least one concussion in the past year. Injury rate based on ‘most serious injury’ reported was highest in ringette (42.9 injuries/100 students/year) and rugby (40.0). The top three most serious injury locations were the knee (24.7%), ankle (21.6%) and head (16.1%). The most common injury types were joint or ligament sprain (26.7%), fracture (13.0%) and concussion (11.8%). Based on all serious injuries reported in female team sports, 73.4% occurred via contact mechanisms (with someone or something). Overuse (16.2%) was the next most common mechanism reported. Of participants that reported concussion as their most serious injury, 100% were attributed to contact mechanisms (38.9% contact with someone; 61.1% contact with something).

Conclusions Team sport injury rates are high in female high school students. Specific consideration of contact injury mechanisms in female youth team sports will inform development and evaluation of targeted female contact and sport-specific prevention strategies.

PREVALENCE OF MENSTRUAL DISORDERS AMONG GERMAN FEMALE ELITE ATHLETES

1Elisabeth M Kirschbaum, 2Katharina Fischer, 3Jan C Wuestenfeld, 4Bernd Wolfarth.

Background A healthy menstrual cycle affects the athletic performance in training and competition. However, the prevalence of menstrual cycle disorders among elite athletes is unclear.

Objective To assess the prevalence of menstrual disorders among German female elite athletes in 2019 and 2020.

Design Retrospective cohort study.

Setting German female youth and adult elite athletes.

Participants 532 female elite athletes (19.5 ± 5.0 years; 170.0 ± 7.3 cm; 62.1 ± 11.4 kg) were included in this study. All athletes were members of the German funding for high performance sports.

Assessment of Risk Factors Menstrual disorder, sport discipline, age, BMI, body fat, training volume.

Main Outcome Measurements All athletes completed a baseline gynecological survey. The independent samples t-test and ANOVA were used for statistical analysis (p<.05).

Results 118 of all 532 of the female athletes (22.2%) had an irregular menstrual cycle. The most prevalent menstrual disorders were oligomenorrhea (41.9%), secondary amenorrhea (25.0%), primary amenorrhea (11.3%), dysmenorrhea (4.0%), metrorrhagia (2.4%), hypermenorrhea (1.6%), polymenorrhea (0.8%) and others (12.9%). There is a significant difference in the prevalence of menstrual disorders among sport disciplines (p=.000, f=.204). The highest prevalence of menstrual disorders occurs among endurance sport athletes (30.9%). Athletes with menstrual disorders have a significantly lower BMI (p=.014, d=.258) and lower percent body fat (p=.000, d=.392) compared to athletes with normal menstrual cycles. There is no significant difference in age (p=.101, d=.172) and training volume (p=.100, d=.172) between the groups.

Conclusions Our research showed a high prevalence of menstrual disorders among German female elite athletes. The results suggest that especially athletes with low BMI and low percent body fat are at a high risk for menstrual disorders. Further research is required to investigate the effects of menstrual disorders on athletic performance and long-term health.
