The following societies have endorsed this statement: American Institute of Ultrasound in Medicine, American Medical Society for Sports Medicine, American Orthopaedic Society for Sports Medicine, American Society of Regional Anesthesia and Pain Medicine, European Society of Musculoskeletal Radiology, Society of Interventional Radiology and Society of Skeletal Radiology. The American Academy of Physical Medicine and Rehabilitation has affirmed the value of the statement.

INTRODUCTION

The use of ultrasound for diagnostic imaging and procedural guidance in musculoskeletal and sports medicine has increased dramatically and involves multiple disciplines and subspecialties. A lack of consensus regarding standardised terminology can lead to confusion when conveying information between colleagues for clinical and research purposes. Our learners often struggle as different terms and definitions are used to describe their work. For example, a significant portion of the musculoskeletal and sports ultrasound community regards ultrasound as a diagnostic modality and a tool for treatment guidance. It is important to note that this terminology varies from specialty to specialty. However, the current lack of agreement regarding standardised terminology presents challenges in education, clinical practice and research.

ABSTRACT

The current lack of agreement regarding standardised terminology in musculoskeletal and sports ultrasound presents challenges in education, clinical practice and research. This consensus was developed to provide a reference to improve clarity and consistency in communication. A multidisciplinary expert panel was convened consisting of 18 members representing multiple specialty societies identified as key stakeholders in musculoskeletal and sports ultrasound. A Delphi process was used to reach consensus, which was defined as group level agreement of >80%. Content was organised into seven general topics including: (1) general definitions, (2) equipment and transducer manipulation, (3) anatomical and descriptive terminology, (4) pathology, (5) procedural terminology, (6) image labelling and (7) documentation. Terms and definitions which reached consensus agreement are presented herein. The historic use of multiple similar terms in the absence of precise definitions has led to confusion when conveying information between colleagues, patients and third-party payers. This multidisciplinary expert consensus addresses multiple areas of variability in diagnostic ultrasound imaging and ultrasound-guided procedures related to musculoskeletal and sports medicine.

Table 1 General definitions

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Musculoskeletal ultrasound</td>
<td>The use of ultrasound to diagnose and/or guide treatment of conditions involving bones, joints, tendons, muscles, bursae, ligaments, cartilage, nerves, fascia and related soft tissue structures. Indications and specifications are outlined in the AIUM Practice Parameter for the Performance of a Musculoskeletal Ultrasound Examination,4 the AIUM Practice Parameter for the Performance of Selected Ultrasound-Guided Procedures5 and the ESSR Musculoskeletal Ultrasound Technical Guidelines.6</td>
</tr>
<tr>
<td>Sports ultrasound</td>
<td>The use of ultrasound by a qualified medical professional to diagnose and/or guide treatment for injuries and medical conditions associated with sport and exercise. This may involve both clinical and in-the-field applications. Sports ultrasound evaluations are most often performed to answer a specific clinical question, and the need for further imaging or involvement of other medical imaging experts should be considered.</td>
</tr>

Table 2 Equipment and transducer manipulation

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equipment</td>
<td>The hand-held device with which one obtains ultrasound images</td>
</tr>
<tr>
<td>Transducer</td>
<td>The connection of the hand-held ultrasound device to the machine or viewing device (if not wireless)</td>
</tr>
<tr>
<td>Transducer manipulation</td>
<td></td>
</tr>
<tr>
<td>Slide</td>
<td>Motion of the transducer across the body surface in any direction</td>
</tr>
<tr>
<td>Heel–toe</td>
<td>Motion in the long axis of the transducer along a fixed point changing the angle of insonation away from 90° to the skin surface while maintaining contact with the skin surface, often used to achieve an angle of insonation at 90° to the target structure to optimise visualisation and eliminate anisotropy</td>
</tr>
<tr>
<td>Tilt</td>
<td>Motion in the short axis of the transducer along a fixed point changing the angle of insonation away from 90° to the skin surface while maintaining contact with the skin surface, often used to achieve an angle of insonation at 90° to the target structure to optimise visualisation and eliminate anisotropy</td>
</tr>
<tr>
<td>Compression</td>
<td>Force is applied by the sonographer or sonologist on the transducer towards the patient’s body.</td>
</tr>
<tr>
<td>Rotation</td>
<td>Motion along a fixed centre axis point of the transducer in the clockwise or counterclockwise direction</td>
</tr>
<tr>
<td>Pivot</td>
<td>Motion along a fixed axis point at the end of the transducer in the clockwise or counterclockwise direction</td>
</tr>
<tr>
<td>Stand off</td>
<td>The transducer does not touch the skin surface but rests on a layer of acoustic coupling gel or other acoustic medium with an angle of insonation at 90° to the skin surface.</td>
</tr>
<tr>
<td>Oblique stand off</td>
<td>The transducer does not touch the skin surface but rests on a layer of acoustic coupling gel or other acoustic medium with an angle of insonation away from 90° to the skin surface.</td>
</tr>
<tr>
<td>Sonopalpation</td>
<td>Force is applied on the transducer towards the patient’s body to elicit symptom provocation (eg, pain).</td>
</tr>
</tbody>
</table>

Table 3 Anatomical and descriptive terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Body planes</td>
<td></td>
</tr>
<tr>
<td>Transverse</td>
<td>Anatomical region (eg, knee) when displayed in cross-section to the region</td>
</tr>
<tr>
<td>Longitudinal</td>
<td>Anatomical region (eg, knee) when displayed parallel to the region lengthwise; when used to refer to an anatomical region, may refer to either the coronal or sagittal plane</td>
</tr>
<tr>
<td>Coronal (frontal) image plane</td>
<td>Any plane perpendicular to a sagittal plane and parallel to the long axis of the body; each coronal image plane extends from left to right through the body.</td>
</tr>
<tr>
<td>Sagittal image plane</td>
<td>The anteroposterior plane parallel to the long axis of the body and passing through the midline; anteroposterior planes not passing through the centre of the body are frequently called parasagittal planes.</td>
</tr>
<tr>
<td>Transverse image plane</td>
<td>A plane perpendicular to the long axis of the body or structure of interest; with respect to the body, a transverse plane extends from left to right and divides the body into superior and inferior regions.</td>
</tr>
<tr>
<td>Axes</td>
<td></td>
</tr>
<tr>
<td>Short axis or transverse</td>
<td>Target structure (eg, Achilles tendon) when displayed in cross-section perpendicular to the structure’s length</td>
</tr>
<tr>
<td>Long axis or longitudinal</td>
<td>Target structure (eg, Achilles tendon) when displayed parallel to the structure’s length</td>
</tr>
<tr>
<td>Directional terms</td>
<td></td>
</tr>
<tr>
<td>Proximal/distal</td>
<td>Describes a position that is closer (proximal) or farther (distal) from the centre of the body</td>
</tr>
<tr>
<td>Anterior/posterior</td>
<td>Direction toward (anterior) or away from (posterior) the front of the trunk or limb (excluding the forearm, hand and foot)</td>
</tr>
<tr>
<td>Superior/inferior</td>
<td>Direction above or towards (superior) or below or away from (inferior) the head</td>
</tr>
<tr>
<td>Medial/lateral</td>
<td>Direction toward the tibia (medial) or toward the fibula (lateral) when describing structures below the knee</td>
</tr>
<tr>
<td>Ulnar/radial</td>
<td>Direction toward the ulna (ulnar) or toward the radius (radial) when describing structures in the forearm, wrist and hand</td>
</tr>
<tr>
<td>Volar/dorsal</td>
<td>Anterior (volar) or posterior (dorsal) surface of the forearm</td>
</tr>
<tr>
<td>Palmar/dorsal</td>
<td>Anterior (palmar) or posterior (dorsal) surface of the hand and wrist</td>
</tr>
<tr>
<td>Plantar/dorsal</td>
<td>Sole (plantar) or top (dorsal) surface of the foot</td>
</tr>
</tbody>
</table>

*All anatomical terms are defined with the body in the anatomical position.

METHODS
Expert group selection and demographics

The project was approved by the board of directors of the American Institute of Ultrasound in Medicine (AIUM) and the American Medical Society for Sports Medicine (AMSSM) who served as the lead societies for this article. Members were invited to represent a diverse group of physicians with experience in the musculoskeletal and sports medicine applications of ultrasound. The AIUM and AMSSM reached out to multiple societies identified to be key stakeholders with the following societies contributing members: American Academy of Orthopaedic Surgeons, American Academy of Physical Medicine & Rehabilitation, American Orthopaedic Society for Sports Medicine, American Society of Regional Anaesthesia and Pain Medicine, European Society of Musculoskeletal Radiology, Society of Interventional Radiology and Society of Skeletal Radiology. Primary specialties represented include anaesthesia, emergency medicine, family medicine, physical medicine and rehabilitation, orthopaedic surgery and radiology.

termology references are available, our focus was on clinically relevant topics in the context of musculoskeletal medicine, where we identified frequent variations in terminology used in everyday practice, scientific presentations and the literature. Our goal was to present a user-friendly reference of the most common terminology encountered in musculoskeletal and sports ultrasound.

Figure 1 (A) Slide, (B) heel–toe, (C) tilt, (D) compression, (E) rotation, (F) pivot, (G) stand-off and (H) oblique stand-off.

<tr>
<td><strong>(A) Tendon</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Tendinopathy&lt;sup&gt;9–12&lt;/sup&gt;</td>
<td>A clinical term used to describe painful conditions of the tendon or tendon sheath including tendinosis, tendinitis and tendon tear</td>
<td></td>
<td>The use of a more precise term is recommended when describing imaging findings if possible.</td>
</tr>
<tr>
<td>Tendinosis&lt;sup&gt;9&lt;/sup&gt;</td>
<td>A chronic tendon condition characterised histologically as collagen degeneration (predominantly mucoid) with other variable features such as collagen disorganisation, fibrocartilaginous metaplasia, calcification and possible neovascularity; primarily an overused and degenerative process with absence of an acute inflammatory infiltrate, but inflammatory mediators may be present</td>
<td>Abnormally hypoechoic tendon without tendon fibre disruption, with possible increase in tendon diameter, with or without flow on Doppler imaging (figure 2A)</td>
<td></td>
</tr>
<tr>
<td>Tendinitis&lt;sup&gt;11–12&lt;/sup&gt;</td>
<td>Tendon inflammation.</td>
<td>Abnormally hypoechoic tendon occasionally associated with possible increased flow on Doppler imaging</td>
<td>Imaging features of tendinosis and tendinitis are similar and may be difficult to differentiate. Features of tendinosis and tendinitis may be present concurrently. Hypoechoaemia, as seen in tendinosis, is due to neovascularity and should not be equated with acute inflammation. Clinical features (such as history of inflammatory disease) may be required to determine the most likely histological diagnosis.</td>
</tr>
<tr>
<td><strong>(B) Muscle</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Strain&lt;sup&gt;26&lt;/sup&gt;</td>
<td>A clinical/biomechanical term which is not well defined and used inconsistently for different muscle injuries</td>
<td></td>
<td>Generally, refers to an elongation or stretch type of injury</td>
</tr>
<tr>
<td>Tear&lt;sup&gt;22–25&lt;/sup&gt;</td>
<td>Injury to muscle fibres or internal aponereoses</td>
<td>Variable, depending on degree of injury ranging from increased echogenicity of intact muscle to muscle or musculotendinous disruption (partial or complete) with possible haemorrhage of variable echogenicity. Possible increased flow on Doppler imaging (figure 3A.1, A.2)</td>
<td>Numerous clinical and imaging-based classification and grading systems for muscle injury exist.</td>
</tr>
<tr>
<td>Contusion&lt;sup&gt;27–29&lt;/sup&gt;</td>
<td>Muscle injury with or without haematoma most commonly as a result of blunt trauma</td>
<td>Mixed echogenicity area of muscle fibre disruption ranging from hyperechoic when acute to anechoic when chronic with possible mass effect from haematoma, possible increased flow on Doppler imaging (figure 3B)</td>
<td>Radiograph or CT scan may be required to confirm the peripheral mineralisation when shadowing does not allow accurate characterisation</td>
</tr>
<tr>
<td>Myositis ossificans&lt;sup&gt;27,28,30&lt;/sup&gt;</td>
<td>A subtype of heterotopic ossification located within muscle most commonly occurring after trauma, often preceded by haematoma</td>
<td>Hyperechoic in early phase followed by a hyperechoic mass-like area within muscle, with hyperechoic foca maturing into an echogenic peripheral rim with possible acoustic shadowing. Possible increased flow on Doppler imaging (figure 3C)</td>
<td></td>
</tr>

**Figure 2** (A) Tendinosis: long-axis image of midportion Achilles tendonosis. Note fusiform thickening (arrowheads) without fibre disruption. (B) Calcific tendinopathy: long-axis image of calcific tendinosis of the ACH insertion. The well-defined hypoechogenic focus (arrow) demonstrates intermediate posterior acoustic shadowing. (C) Tenosynovitis: short-axis image of the AT demonstrating distension of the tendon sheath (asterisks) with increased Doppler flow. (D) Stenosening tenosynovitis: long-axis view of the first dorsal compartment of the wrist. The retinaculum (double arrow) is hypoechogenic and significantly thickened with hyperaemia on Doppler. (E) Paratenonitis: short axis image of the ACH. There is focal hypoechogenic thickening of the lateral aspect of the paratenon (open arrows) with hyperaemia on Doppler. (F) Tendon tear: long-axis extended field of view image of acute PT complete tear. There is loss of tension with a hypoechogenic region of tendon fibre disruption (arrowhead). Edge shadowing artefact (arrows) is noted deep to the proximal tendon stump. ACH, Achilles tendon; APL, abductor pollicis longus tendon; AT, anterior tibialis tendon; CALC, calcaneus; PAT, patella; PT, patellar tendon; TIB, tibia.

**Figure 3** (A) Muscle tear: (1) long-axis image of the RF demonstrating an acute disruption of the central aponeurosis and surrounding muscle (callipers); there is anechoic haemorrhagic fluid (asterisks) at the site of tear; (2) corresponding short-axis image. (B) Muscle contusion: long-axis extended field of view image of an acute quadriceps contusion. Muscle fibre disruption of the VI is noted with a large anechoic haematoma (asterisks) resulting in mass effect. (C) Myositis ossificans: long-axis image of the quadriceps. This follow-up image of the muscle contusion (B) demonstrates resolution of haematoma with formation of hyperechoic regions of myositis ossificans (arrows). (D) Muscle fatty infiltration: short-axis extended field of view image of the rotator cuff musculature in setting of chronic complete rotator cuff tear. The SS and IS are diffusely hypoechogenic with loss of internal muscle fibre definition. FEM, femur; IS, infraspinatus; RF, rectus femoris; SS, supraspinatus; TM, teres minor; TRAP, trapezius; VI, vastus intermedius.

**Consensus statement**

A list of general topics to be included was discussed among the group and organised as presented in box 1. Each section was then assigned to a small working group who was responsible for identifying key references and creating the initial list of terms to be defined. This was circulated among the group until agreement was reached on final terms to be included. Each small group was
then responsible for drafting the working definitions. The list of terms, definitions and key references for each section was then made available to the group for review prior to the initiation of the Delphi procedure.

**Delphi procedure**

A Delphi method was used to reduce ‘group think’ bias by allowing anonymous voting and comments. The group leader (MMH) was responsible for developing and distributing all surveys and moderating discussion among the group. Qualtrics

**Figure 4** (A) Ligament tear: long-axis image of an acute UCL tear. A hyperechoic region of fibre disruption and haematoma (asterisks) is noted proximal. The distal attachment is intact but thickened (open arrows) and a hyperechoic linear density (solid arrow) overlying the joint space represents chronic calcific changes. Also note an associated muscle injury of the flexor/pronator group (arrowheads). (B) Ligament tear: long-axis image of acute anterior talofibular ligament (arrows) tear. Loss of tension results in an atypical contour of the ligament (open arrow). This can be further confirmed with dynamic stress imaging. FIB, fibula; HUM, humerus; UCL, ulnar collateral ligament; ULN, ulna; TAL, talus.

**Figure 5** (A) Joint effusion: long-axis image of the suprapatellar recess with anechoic fluid distension (asterisk) representing a simple joint effusion. (B) Synovial proliferation: long-axis image of the anterior ankle with hypoechoic synovial tissue hypertrophy (arrows) without Doppler flow. (C) Synovitis: long-axis image of the dorsal wrist demonstrating hypoechoic synovial tissue with increased Doppler flow in the setting of rheumatoid arthritis. CAP, capitate; RAD, radius; PAT, patella; QT, quadriceps tendon; TAL, talus; TIB, tibia.

**Figure 6** (A) Compression neuropathy: long-axis image of the median nerve (arrows) at the carpal tunnel. Significant swelling is noted proximal to the compression site (open arrow). (B) Nerve transection: long-axis image of complete ulnar nerve transection. Note discontinuity of nerve with retraction (callipers) and thickening at the ends representing stump neuromas (asterisks). (C) Neuroma: long-axis image of a partial transection of the lateral antebrachial cutaneous nerve (arrows). Focal hypoechoic enlargement (arrowhead) represents a neuroma at the site of injury. MN, median nerve; UN, ulnar nerve.

**Figure 7** Fasciosis: long-axis image of the plantar fascia. Thickening of the origin is noted (double arrow) with focal hypoechoic regions (asterisks) representing degenerative changes. CALC, calcaneus; PF, plantar fascia.
Peppering This term has been used to describe a type of fenestration procedure (often involving a tendon) alone or in conjunction with an injection. The use of more precise terms such as ‘tenotomy’, ‘fasciotomy’ or ‘fenestration’ is recommended.

Needling This is an inconsistent term that has been used to describe a range of procedures from dry needling of myofascial trigger points to tenotomy or fasciotomy. The term ‘needling’ should only be used in conjunction with ‘dry needling’ as previously defined.

Stylet movement Small movements of a stylet in and out of the tip of the needle to improve needle tip visualisation; the stylet should not be modified to allow it to advance beyond the needle tip when using this technique for visualisation.

**Procedure technique descriptions**

**Aponeurotomy** Cutting an aponeurosis, either completely or incompletely, using a needle, scalpel or other device.

**Aspiration** The act of delivering a fluid or other substance into the body, typically using a needle and syringe, catheter or other device.

**Barbotage** Repeated injection and aspiration of fluid to break up and remove calcification, usually within a tendon.

**Brisement** The injection of fluid into the space between a tendon and its paratenon or sheath; brisement has also been used to refer to injection of saline or other fluid into a joint to break down adhesions (eg, in treatment of adhesive capsulitis).

**Debridement** The removal of necrotic, degenerative or infected tissue from a region or given tissue of the body.

**Dry needling** A procedure, generally used as part of manual physical therapy, where a small gauge needle is inserted into a muscle or other soft tissue structure to treat myofascial pain.

**Fasciotomy** Cutting fascia, either completely or incompletely, using a needle, scalpel or other device.

**Fenestration** The act of repetitive puncture of a soft tissue structure with a needle or other device.

**Fragmentation** The use of a needle or other device to break up calcified or bony tissue.

**Hydrodissection** Technique by which saline or other sterile fluid is injected to separate tissues or tissue planes from each other.

**Injection** The act of delivering a fluid or other substance into the body, typically using a needle and syringe, catheter or other device.

**Lavage** Washing out using saline or other sterile solution; irrigation is an acceptable alternate term.

**Neurolysis** There are distinct definitions of neurolysis. An appropriate modifier is recommended to clearly describe the procedure performed.

**Surgical neurolysis** The surgical freeing of nerves from surrounding tissue/adhesion.

**Hydroneurolysis** The injection of saline or other sterile fluid to free nerves from surrounding tissue/adhesion; the term ‘nerve hydrodissection’ is an acceptable alternate term.

**Chemical neurolysis** The application of chemical agents to a nerve in order to cause temporary or permanent degeneration of targeted nerve fibres.

**Lavage** Washing out using saline or other sterile solution; irrigation is an acceptable alternate term.

**Neurolysis** There are distinct definitions of neurolysis. An appropriate modifier is recommended to clearly describe the procedure performed.

**Chemical neurolysis** The application of chemical agents to a nerve in order to cause temporary or permanent degeneration of targeted nerve fibres.

**Physical neurolysis** The application of physical energy (eg, heat or cold) to a nerve in order to cause temporary or permanent degeneration of the targeted nerve fibres.

**Pliant fasciectomy** Cutting the plantar fascia, either completely or incompletely, using a needle, scalpel or other device.

**Tendon scraping** The process of abrading the surface of a tendon or paratenon with a needle, scalpel, or other device, with the goal of separating the tendon from neovessels, neoneurons and/or adjacent soft tissues.

**Tenotomy** Cutting tendon tissue, either completely or incompletely, using a needle, scalpel or other device.

**Trigger finger release** Cutting the pulley and associated tendon sheath responsible for the stenosis using a needle, scalpel or other device.

**Terms to avoid**

**Minimally invasive, ultraminimally invasive and microinvasive** These are relative and imprecise terms without formal definitions. Therefore, their use is not recommended. The exact procedure should be described including technique and tool(s) used.

**Needling** This is an inconsistent term that has been used to describe a range of procedures from dry needling of myofascial trigger points to tenotomy or fasciotomy procedures. The use of a more precise term is recommended. ‘Needling’ should only be used in conjunction with ‘dry needling’ as previously defined.

**Peppering** This term has been used to describe a type of fenestration procedure (often involving a tendon) alone or in conjunction with an injection. The use of more precise terms such as ‘tenotomy’, ‘fasciotomy’ or ‘fenestration’ is recommended.

**Percutaneous** This term refers to a procedure performed through the skin. Due to lack of specificity associated with this term, its use in isolation is not recommended. Rather, the exact procedural technique should be described including tool(s) used and approach.

### Box 2 Template for documenting a diagnostic US examination

2. Date and time of examination.
3. Ordering provider.
4. Location and contact information of facility in which the diagnostic US was performed.
5. Clinical history/indication.
6. Description of diagnostic US study performed.
   - Anatomical location.
   - Complete or limited exam.
7. Findings.
8. Impression/conclusion/summary.

*When reporting a diagnostic US, all structures evaluated should be specifically mentioned in the ‘findings’ section or elsewhere in the report, even if within normal limits.

US, ultrasound.
Consensus statement

Equipment and transducer manipulation
When instructing or discussing ultrasound technique, consistency in terminology used to describe transducer movement and manipulation is critical to avoid confusion and to facilitate effective communication. Although prior authors have made recommendations, these have not been universally accepted. Furthermore, we identified ongoing confusion regarding cardinal movements as well as additional terms relevant to musculoskeletal and sports medicine practice as listed in table 2. Of note, we concluded that using a single term, ‘slide’, to describe moving the transducer from point A to point B was most clear. Further directional or anatomical descriptors may need to be added to provide clarity. These terms are discussed as follows and demonstrated in figure 1.

Anatomical and descriptive terminology
Table 3 lists recommended anatomical and descriptive terms. There was agreement with the imaging plane definitions presented in the AIUM Recommended Ultrasound Terminology document. When discussing body planes in relation to the anatomical region of interest, the group was unable to arrive at a consensus for a single term to describe parallel longitudinal planes. Either coronal/sagittal or longitudinal were proposed as appropriate terms. Similarly, when discussing axes of the target structure, we could not reach consensus on a single best term. Short axis and transverse can be used interchangeably as can long axis and longitudinal.

Pathology
Pathology terms have been divided into groups based on anatomical tissue type with consensus recommendations presented in table 4. Representative images demonstrating key terms can be found in figures 2–7. These terms are not meant to be prescriptive but rather represent the current best terms based on the literature and our expert opinion. We recognise that our understanding of pathophysiologial processes is in constant evolution, and certain terms may require modifications based on future research. We focused on the accepted ultrasound appearance of common pathologies, recognising that pathognomonic ultrasound findings do not currently exist for all histopathological conditions. Furthermore, certain clinical conditions may be difficult to differentiate based on imaging features alone. Similarly, although Doppler flow is often considered a key imaging finding for some pathological conditions (eg, synovitis, tendinitis, etc), we agreed that, due to variability in both equipment and technique, the presence or absence of Doppler flow should not be an absolute requirement. Rather, we highlight when Doppler flow may be expected and further supports a specific diagnosis.

Procedural
Like the pathology section, the procedural terms and definitions presented in table 5 attempt to reconcile the historic use of multiple similar terms in the absence of precise definitions. This has resulted in difficulties interpreting clinical outcomes and conveying procedural techniques both to colleagues and third-party payers. Our goal is for these core terms to be used with appropriate technical descriptors bringing more consistency to procedural reporting.

Image labeling
There was consensus agreement that all ultrasound images should include labels identifying the target structure or region and laterality as appropriate. Other considerations which did not reach consensus but had majority agreement include (1) orientation of the image relative to the target structure or region (long axis, short axis, etc); (2) directional orientation (medial, lateral, proximal, distal, etc); (3) directional descriptors for cine loops (proximal to distal, medial to lateral, etc).

Documentation
The templates in boxes 2 and 3 include the key components which should be considered when documenting a diagnostic ultrasound or ultrasound-guided procedure. Notably, they are not meant to replace local institutional guidelines or policies regarding documentation of ultrasound-related services. These recommendations pertain to all billable ultrasound services performed in any setting. If studies are performed as a non-billable service (eg, in the athletic training room), then individual institutional guidelines and standards should be developed regarding documentation and image archiving. If any information populates the electronic medical record or images automatically, it does not need to be included separately in the report.

CONCLUSION
The historic use of multiple similar terms in the absence of precise definitions has led to confusion when conveying...
information between colleagues, patients and third-party payers. This multidisciplinary expert consensus addresses multiple areas of variability in diagnostic ultrasound imaging and ultrasound-guided procedures related to musculoskeletal and sports medicine. This concise reference should improve clarity and consistency of communication and reporting.
